

homalg

A META-PACKAGE FOR HOMOLOGICAL ALGEBRA

MOHAMED BARAKAT & DANIEL ROBERTZ

ABSTRACT. The central notion of this work is that of a functor between categories of finitely presented modules over so-called computable rings, i.e. rings R where one can algorithmically solve inhomogeneous linear equations with coefficients in R . The paper describes a way allowing one to realize such functors, e.g. Hom_R , $\otimes_R$, Ext_R^i , Tor_i^R , as a mathematical object in a computer algebra system. Once this is achieved, one can compose and derive functors and even iterate this process without the need of any specific knowledge of these functors. These ideas are realized in the ring independent package **homalg**. It is designed to extend any computer algebra software implementing the arithmetics of a computable ring R , as soon as the latter contains algorithms to solve inhomogeneous linear equations with coefficients in R . Beside explaining how this suffices, the paper describes the nature of the extensions provided by **homalg**.

1. INTRODUCTION

In the setup of finitely presented module categories, **homalg** realizes functors as mathematical objects which, up to now, can be composed and derived. To this end it realizes, unlike all present systems, the functors not only by the object part, but *automatically* also by the morphism part.

homalg is abstractly designed and therefore can be used as an extension of other mathematical software providing the necessary ring arithmetics in any concrete problem.

1.1. homalg as a programming environment for homological algebra. Functors map objects of a source category to objects of a target category and, in a compatible way, morphisms between two objects in the source category to morphisms between their images in the target category. So when one implements a functor one has not only to take care of how it acts on objects, but also of how it acts on morphisms between these objects.

Homological algebraic constructions [CE99, HS97, MR01, Rot79, Wei94] are present in most of the computer algebra systems such as Macaulay 2 [GS], Singular [GPS05]/Plural [LS03], and CoCoA [CoC]. One can often find a procedure, let us call it Hom , to compute $\text{Hom}_R(A, B)$ for two finitely presented modules A and B over commutative rings that are implemented in these systems. Now given two further modules M and N and a morphism $M \xrightarrow{\varphi} N$, what about applying $\text{Hom}_R(A, -)$ or $\text{Hom}_R(-, B)$ to the morphism φ ? Mathematically it is clear how $\text{Hom}_R(A, -)$ or $\text{Hom}_R(-, B)$ induces a morphism $\text{Hom}_R(A, M) \xrightarrow{\text{Hom}_R(A, \varphi)} \text{Hom}_R(A, N)$ or $\text{Hom}_R(N, B) \xrightarrow{\text{Hom}_R(\varphi, B)} \text{Hom}_R(M, B)$, but on

the level of a computer implementation the information to compute these induced morphisms is normally not contained in the procedure `Hom`. So one needs to write or find two completely independent procedures, say `HomMap` and `Hom2Map` implementing the computations of the induced morphisms. `HomMap` is for example essential¹ if one wants to compute $\text{Ext}_R^i(A, B) := R^i \text{Hom}_R(-, B)(A)$, the i^{th} right derived functor of $\text{Hom}_R(-, B)$ applied to A . Again, a procedure, let us call it `Ext`, implementing for all i the computation of the extension modules $\text{Ext}_R^i(A, B)$ is normally not of much help when it comes to computing the induced morphisms $\text{Ext}_R^i(\varphi, B)$ or $\text{Ext}_R^i(A, \varphi)$. Writing the corresponding procedures, say `ExtMap` and `Ext2Map`, requires one to know about the derivation process, and of course to have `Hom`, `HomMap` and `Hom2Map` predefined. So what about composing functors? Consider $\text{Ext}_R^j(\text{Ext}_R^k(-, -), -)$ for example (cf. [Roo62], [Bjö79, p. 58ff]). For the object part one needs to compose the procedure `Ext` with itself using the first argument. Let us call this compositum `ExtExt`. The morphism part has now three components. Let us consider $\text{Ext}_R^j(\text{Ext}_R^k(A, -), B)$ for example. Again, a procedure `ExtExt` is offhand not of much help. For this morphism part one rather needs a predefined `Ext2Map` to first compute $\psi := \text{Ext}_R^k(A, \varphi)$, then a predefined `ExtMap` to compute $\text{Ext}_R^j(\psi, B)$. Let us call the resulting procedure `ExtExt2Map`.

So in order to derive or compose functors, one needs their part on objects but also their part on morphisms. This means, that for each functor one has to implement one procedure for the object part and as many procedures as needed for the morphism part. For more complex functors, constructed out of given ones via iterated compositions and derivations² this quickly becomes unfeasable. So on the level of the computer implementation the following became unavoidable:

- Include the mathematical information of how the bifunctor $\text{Hom}_R(-, -)$ acts on morphisms inside the procedure `Hom` itself. This has to be done in a way, that a general procedure, say `FunctorMap`, is able to extract this information out of `Hom`. Further `HomMap` and `Hom2Map` should now be defined only using `FunctorMap` applied to `Hom`.
- Implement a general right derivation procedure for a contravariant functor (given by both its parts), let us call it `RightDerivedCofunctor`. Now define `Ext` only using `RightDerivedCofunctor` applied to the `Hom`-functor given by both³ its parts `[Hom, [HomMap, Hom2Map]]`. The procedure `Ext`, or rather the derivation procedure used to define `Ext`, should be able to reconstruct the mathematical information of how the bifunctor $\text{Ext}_R(-, -)$ acts on morphisms, and this in such a way that the same procedure `FunctorMap` mentioned above is able to extract this information out of `Ext`. The derivation procedure should reconstruct this information alone from

¹Maybe not in full generality, since one only needs to apply $\text{Hom}_R(-, B)$ to morphisms between free modules $R^{1 \times l_i} \xrightarrow{\varphi} R^{1 \times l'_i}$.

²Left derivation for covariant functors and right derivation for contravariant functors (=cofunctors).

³Since we right derive $\text{Hom}_R(-, -)$ with respect to its first argument, the corresponding morphism procedure `HomMap` has to be marked in the input of `RightDerivedCofunctor`. This is a minor technical issue.

its input $[\text{Hom}, [\overline{\text{HomMap}}, \text{Hom2Map}]]$. ExtMap and Ext2Map should now be defined only using FunctorMap applied to Ext .

- Implement a general composition procedure for two functors (given by both their parts), let us call it **ComposeFunctors**. Then define ExtExt only using **ComposeFunctors** applied⁴ to $[\text{Ext}, [\overline{\text{ExtMap}}, \text{Ext2Map}]]$ and $[\text{Ext}, [\text{ExtMap}, \text{Ext2Map}]]$. The procedure ExtExt , or rather the composition procedure used to define ExtExt , should be able to reconstruct the mathematical information of how the trifunctor $\text{Ext}_R^j(\text{Ext}_R^k(-, -), -)$ acts on morphisms, in such a way that the same procedure **FunctorMap** as above is able to extract this information out of ExtExt . The composition procedure should reconstruct this information, alone out of its input, which is here $[\text{Ext}, [\overline{\text{ExtMap}}, \text{Ext2Map}]]$ and $[\text{Ext}, [\text{ExtMap}, \text{Ext2Map}]]$. Again, ExtExtMap , ExtExt2Map and ExtExt3Map should now be defined only using **FunctorMap** applied to ExtExt .

Like **FunctorMap**, the procedures **RightDerivedCofunctor** and **ComposeFunctors** should be implemented in a way that is independent of the functors they are applied to. So, with the same **RightDerivedCofunctor** one should be able to define $R^i \text{Ext}_R^j(\text{Ext}_R^k(A, -), B)$ and again with the same **FunctorMap** compute its part on morphisms, etc.

Starting from Section 5 we will try to isolate the mathematical ideas that helped us to realize functors as mathematical objects. That defining more complex functors in *both* their parts is now an easy, even automatic task is the *first defining property* of **homalg**.

1.2. homalg as a meta-package. Not a single algorithm to compute in any sort of *rings* is implemented in **homalg**. Rather it is a package built up of homological algebraic definitions and constructions. On the highest levels one finds the construction of connecting homomorphisms and long exact sequences, the processes of composition and derivation of functors and definitions of various specific functors. On lower levels **homalg** goes all the way down till it reaches two procedures, which are basically the only ones required from any software implementing the ring specific arithmetics of the (not necessarily commutative) ring R . In what follows we refer by “*ring package*” to such software. To describe the two procedures let K be a (left) R -submodule of the free module $R^{1 \times n}$ given by finitely many generators. Further let $\mathbf{b}$ be an arbitrary element of $R^{1 \times n}$ and A an R -submodule of K , again given by finitely many generators ($A \leq K \leq R^{1 \times n} \ni \mathbf{b}$). Let $\mathbf{M} \in R^{k \times n}$ resp. $\mathbf{N} \in R^{a \times n}$ be the matrix having as rows the generators of K resp. of A .

(Z) The procedure **DecideZero**($\mathbf{b}, \mathbf{M}$):

Effectively decide if $\mathbf{b}$ is an element of K or not. “Effectively” means: In case the element $\mathbf{b}$ belongs to K , then the procedure **DecideZero** returns zero and, if asked to, is able to express $\mathbf{b}$ as an R -linear combination of the generators of M . Otherwise some element $\mathbf{b}' \in \mathbf{b} + K$ is returned. This is equivalent to deciding the solvability of the inhomogeneous R -linear system $\mathbf{xM} = \mathbf{b}$ and, if asked to, finding a

⁴Since we compose $\text{Ext}_R(-, -)$ (here with itself) with respect to the first argument, the corresponding morphism ExtMap has to be marked in the first argument of **ComposeFunctors**.

particular solution $\mathbf{x} \in R^{1 \times k}$, in case one exists. This is simply the straightforward generalization of the ideal membership problem to submodules.

(S) The procedure **SyzygiesGenerators**($\mathbf{M}, \mathbf{N}$):

Compute a generating set of the R -module of solutions of the homogeneous R -linear system $\mathbf{xM} = 0 \pmod{\mathbf{N}}$. For $\mathbf{z} \in R^{1 \times n}$ the statement $\mathbf{z} = 0 \pmod{\mathbf{N}}$ means that there exists a $\mathbf{y} \in R^{1 \times a}$, such that $\mathbf{z} = \mathbf{yN}$. One calls every such solution a syzygy among the generators of K modulo A .

As the reader may have noticed, it is not required in (Z) that the output $\mathbf{b}'$ of **DecideZero** only depends on $\mathbf{b} + K$, i.e. **homalg** does not require from **DecideZero** to provide a normal form modulo K for every element $\mathbf{b} \in R^{1 \times n}$, except for $\mathbf{b} \in K$, where **DecideZero** *must* return zero. Deciding if two elements $\mathbf{b}, \mathbf{c} \in R^{1 \times n}$ represent the same class modulo K , is reduced to checking if $\mathbf{b} - \mathbf{c} \in K$, i.e. if **DecideZero**($\mathbf{b} - \mathbf{c}, \mathbf{M}$) = 0.

In practice however one often solves (Z) by first constructing a different set of generators for K out of the given one, where this new set satisfies certain properties⁵, such that a reduction algorithm with respect to a set of generators having these properties is available. In what follows we call such a set of generators a *basis* (this should not be confused with a free basis). Normally, such a basis also provides a way to algorithmically solve (S). **homalg** enables the ring package to specify a procedure called **BasisOfModule** to compute such a basis. Internally, **homalg** only uses the procedure **DecideZero** to perform reductions with respect to such a basis. In case the ring package performs reductions without computing such a basis the procedure **BasisOfModule** is to be set to the identity procedure. In what follows we will refer to the output $\mathbf{b}'$ of **DecideZero**($\mathbf{b}, \mathbf{M}$) as the *reduction* of $\mathbf{b}$ modulo K (or modulo $\mathbf{M}$).

Summing up one can say:

- (1) **homalg** is designed to be easily extendable by sparing the user the technical details of homological constructions.
- (2) **homalg** is a meta-package that is designed to easily extend mathematical software implementing ring arithmetics. All what **homalg** needs from such an implementation are two procedures: One to effectively solve the ideal membership problem (Z) and one to compute a generating set of syzygies, i.e. to solve (S) (cf. [Sch80, CLO92, KR00, BGT03, DL06]). We will call such rings *computable*.

We stress the following point: For **homalg** it is irrelevant how (Z) and (S) are solved. Hence, the irrelevance of explaining, or even mentioning how to solve these two problems for every particular class of rings is a defining property of **homalg**, namely its *second defining property*.

In Section 2 we describe the categories **homalg** is dealing with. In Section 3 we deduce from the two procedures **DecideZero** and **SyzygiesGenerators** all the other procedures used in the sequel. After introducing some notation in Section 4 we describe **homalg**'s philosophy of implementing functors in Sections 5 and 6, whereas Section 7 describes how **homalg** derives functors. Appendix A outlines the various ring packages that have been

⁵E.g. a GAUSSIAN triangular basis in case of fields or an involutive or GRÖBNER basis in case of polynomial rings.

successfully used in connection with `homalg`. Appendix B includes some comments to the current implementation. Finally, examples are given in Appendix C. All appendices are available at the site of `homalg` [BR07c].

It goes without saying that we will suppress some technical issues of the package for the sake of mathematical clarity. The best (technical) guide to the package remains its source code, which in nearly all parts can be read as a mathematical text.

2. PRESENTATIONS

Let R be a left noetherian ring with one. Denote by $\mathcal{C}^{\text{mod}}$ the category of finitely generated left R -modules, which is a full subcategory of the abelian category of left R -modules. And denote by $\mathcal{C}^{\text{mat}}$ the category of finite R -presentations with objects being finite dimensional matrices over R , where one identifies two matrices $\mathbf{M} \in R^{l_1 \times l_0}$ and $\mathbf{M}' \in R^{r_1 \times l_0}$ with the same number l_0 of columns to one object, if $R^{1 \times l_1} \mathbf{M} = R^{1 \times r_1} \mathbf{M}'$, as R -submodules of $R^{1 \times l_0}$. The set $\text{Mor}_{\mathcal{C}^{\text{mat}}}(\mathbf{M}, \mathbf{L})$ of morphisms between two objects $\mathbf{M} \in R^{l_1 \times l_0}$ and $\mathbf{L} \in R^{l'_1 \times l'_0}$ is the set of all $l_0 \times l'_0$ R -matrices φ with $R^{1 \times l_1} \mathbf{M} \varphi \leq R^{1 \times l'_1} \mathbf{L}$, where one identifies two matrices φ_1 and φ_2 to one morphism, if they induce the same R -module homomorphism from $\text{coker}(R^{1 \times l_1} \xrightarrow{\mathbf{M}} R^{1 \times l_0}) = R^{1 \times l_0} / R^{1 \times l_1} \mathbf{M}$ to $\text{coker}(R^{1 \times l'_1} \xrightarrow{\mathbf{L}} R^{1 \times l'_0}) = R^{1 \times l'_0} / R^{1 \times l'_1} \mathbf{L}$.

As usual a presentation is given by generators and relations. If one takes the classes of the l_0 standard basis vectors of $R^{1 \times l_0}$ as generators of $M := \text{coker}(R^{1 \times l_1} \xrightarrow{\mathbf{M}} R^{1 \times l_0}) = R^{1 \times l_0} / R^{1 \times l_1} \mathbf{M}$, then the l_1 rows of $\mathbf{M}$ are the defining relations between these generators. We thus call $\mathbf{M}$ a *presentation matrix* or a *relation matrix* for M . Further we call $R^{1 \times l_1} \mathbf{M} = \text{im}(\mathbf{M})$ the *relation subspace for M generated by (the rows of) $\mathbf{M}$* and denote it by $\langle \mathbf{M} \rangle$.

If $\mathbf{M}$ contains a unit in the j^{th} column, then the row containing this unit is a relation expressing the j^{th} generator of $M = \text{coker}(\mathbf{M})$ as an R -linear combination in terms of the other generators. Hence one can, using elementary matrix transformations, rewrite the matrix of relations with respect to the remaining generators and obtain a new relation matrix with one less column (and one less row). One iterates this process until the relation matrix is free of units. So, without loss of generality, one can assume that the relation matrix $\mathbf{M}$ is free of units. For deciding invertability of a ring element and computing its inverse `homalg` uses the procedure `Leftinverse` described in 3.1.3.

Summing up, the functor `coker` that maps

$$R^{l_1 \times l_0} \ni \mathbf{M} \mapsto M := \text{coker}(R^{1 \times l_1} \xrightarrow{\mathbf{M}} R^{1 \times l_0})$$

is an equivalence between the categories $\mathcal{C}^{\text{mat}}$ and $\mathcal{C}^{\text{mod}}$. Its inverse functor is to fix a presentation matrix $\mathbf{M} \in \text{Obj}_{\mathcal{C}^{\text{mat}}}$ for each module $M \in \text{Obj}_{\mathcal{C}^{\text{mod}}}$ and to use the generators of the fixed presentations to express maps in $\text{Mor}_{\mathcal{C}^{\text{mod}}}$ as matrices in $\text{Mor}_{\mathcal{C}^{\text{mat}}}$ (cf. [GP02, p. 101]).

In what follows we no longer distinguish between the two categories and therefore we simply denote both by $\mathcal{C}$.

3. BASIC PROCEDURES

3.1. Procedures based on DecideZero.

3.1.1. **RightDivide**(B, A, L). This procedure is the ring-theoretic version of finding a *particular solution* of an inhomogeneous linear system of equations. Hence, it is not astonishing that in a lot of computations it plays the decisive role (cf. 3.1.2-3.1.4).

For three R -matrices A, B and L with the same number of *columns*, one wants to compute an X with

$$B = XA \pmod{L},$$

i.e. an X, such that there exists a Y with

$$B = XA + YL = (X, Y) \begin{pmatrix} A \\ L \end{pmatrix}.$$

After computing (X, Y) one often simply throws away Y. So without loss of generality we forget about L, i.e. consider the system $B = XA$. To find X one computes a basis G for A (i.e. a matrix G with rows being a basis for the rows of A) together with a matrix C_A , such that $G = C_A A$. Then one reduces B modulo G, i.e. computes a matrix $N := \text{DecideZero}(B, G)$ (cf. 1.2, (Z)), with rows being those of B reduced modulo G. We compute N together with a matrix C_B , such that $N = B + C_B G$. If N is not the zero matrix, then the system is not solvable. Otherwise $X = -C_B C_A$ is a solution. Thinking of X as “ $X = BA^{-1}$ ” justifies the name of the procedure.

The most prominent application of **RightDivide** in **homalg** is the following situation: Given the three modules and the two morphisms

$$\begin{array}{ccc} M' & & \\ & \searrow \gamma & \\ N' & \xrightarrow{\beta} & N \end{array}$$

satisfying the so-called *image condition* $\text{im } \gamma \leq \text{im } \beta$ (as submodules of N), find a third morphism $\psi : M' \rightarrow N'$ that makes the triangle commute. The image condition is obviously a necessary condition for such a ψ to exist. There are two instances of special importance for us in which such a ψ always exists:

- (1) M' is a free module (of finite rank r), or
- (2) β is injective.

In the first case let $(b_1, \dots, b_r)$ be a free basis of M' . Define $b_i \psi$ to be any element of the set $(b_i \gamma) \beta^{-1}$, i.e. any element in the preimage of $b_i \gamma$ under β , and since M' is free on $(b_1, \dots, b_r)$ this extends by linearity to a morphism $\psi : M' \rightarrow N'$ satisfying $\psi \beta = \gamma$. In the second case β is an isomorphism onto $\text{im } \beta$ and one defines $\psi := \gamma \beta^{-1}$, where γ is viewed as a morphism $M' \rightarrow \text{im } \beta$.

Now let M', N' and N be relation matrices of M', N' and N respectively. Then we are looking for a matrix ψ , together with matrices Y and Z such that

- (i) $\gamma = \psi \beta + YN$,

(ii) $M'\psi = ZN'$.

If one regards ψ merely as a matrix, i.e. not necessarily a morphism $M' \rightarrow N'$, then condition (i) is nothing else but the above mentioned image condition. Therefore, for the situation described above, such a matrix γ always exists. But now condition (ii) states that ψ carries the relations of M' to relations of N' , i.e. it requires ψ to be a morphism from M' to N' . While condition (i) is already in the form needed by **RightDivide**⁶, ψ on the left hand side of condition (ii) is multiplied from the right⁷. It now happens that in the two instances (1) and (2) condition (ii) is automatically fulfilled, whenever (i) is. In the first instance one needs to additionally require that M' is given on a free basis. Then the matrix of relations M' is the zero matrix (with one row and r columns), so (ii) is trivially satisfied for any ψ by taking Z to be the zero matrix of appropriate dimension. Case (2) is equivalent to saying that the preimage of the subspace $\langle N \rangle$ of relations for N (generated by N) under β coincides with the subspace $\langle N' \rangle$ of relations for N' (generated by N'): $(\langle N \rangle)\beta^{-1} = \langle N' \rangle$. But since γ is a morphism $M' \rightarrow N$ any relation $m' \in \langle M' \rangle$ of M satisfies $0 = m'\gamma \stackrel{(i)}{=} (m'\psi)\beta \pmod{\langle N \rangle}$. Hence, there exists an $n' \in \langle N' \rangle$, such that $n' = m'\psi$. So ψ takes relations of M' to relations of N' and is hence a morphism $M' \rightarrow N'$.

3.1.2. CompleteImSq. This is the most prominent reincarnation of **RightDivide** in **homalg**. We call an incomplete square of the form

$$\begin{array}{ccc} M' & \xrightarrow{\alpha} & M \\ & & \downarrow \varphi \\ N' & \xrightarrow{\beta} & N \end{array}$$

an *image square* if the image condition $\text{im}(\alpha\varphi) \leq \text{im}(\beta)$ (as submodules of N) is satisfied. This is precisely the above situation for $\gamma = \alpha\varphi$. In Section 5 **CompleteImSq** is applied to image squares with injective β (case (2)) and in Subsection 7.2 to ones where M' is free (case (1)). In these two instances, as shown above, the image square is completable by a morphism $\psi : M' \rightarrow N'$ which is directly computable using **RightDivide**.

3.1.3. Leftinverse. The typical applications of **Leftinverse** correspond to the two situations (1) and (2) described for **RightDivide** in 3.1.1 (cf. Example C.3):

- (1) Either take $M' = N$ *free* (case 3.1.1.(1)), $\gamma = \text{id}$ and $\beta : N' \rightarrow N$ surjective. Then the image condition is trivially satisfied. $\psi : M' = N \rightarrow N'$ is then nothing else but the left inverse or a *split* of β .

⁶Following the notation used in defining **RightDivide** we set $A = \beta$, $B = \gamma$ and $L = N$.

⁷If the ring R is commutative, one can use the **KRONECKER** product to construct for any matrix C over R a matrix $\tilde{C}$ satisfying $\text{row}(CX) = \text{row}(X)\tilde{C}$ for any composable matrix X , where $\text{row}(C)$ is the row vector consisting of the rows of C written behind each other in the obvious order. By this trick one can rewrite the two conditions (i) and (ii) in a single affine condition, where $\text{row}(\psi)$, $\text{row}(Y)$ and $\text{row}(Z)$ are multiplied from the left as required by **RightDivide**. Since the resulting affine system is, in general, much bigger compared with the initial ones solving it is computationally expensive. Cf. [ZL02].

- (2) Or take $M' = N$, $\gamma = \text{id}$ and $\beta : N' \rightarrow N$ an isomorphism. Then in particular β is injective (case 3.1.1.(2)), and the image condition is trivially satisfied. $\psi : M' = N \rightarrow N'$ is then nothing else but the (left)inverse of β .

3.1.4. Preimage. Let $M \xrightarrow{A} L$ be a morphism between the two modules M and $L := \text{coker}(L)$. If the matrix B consists of rows that are in the image of A , i.e. if the image condition is satisfied, then the rows of the matrix X computed by `RightDivide` are the preimages of the rows of B under A . In Subsection 7.4 we use the procedure `Preimage` to construct connecting homomorphisms.

3.2. Procedures additionally based on SyzygiesGenerators. For a matrix $A \in R^{l_1 \times l_0}$ a *matrix of generating syzygies* or a *syzygy matrix* is a matrix $X \in R^{l_2 \times l_1}$ such that $R^{1 \times l_2} X = \ker(R^{1 \times l_1} \xrightarrow{A} R^{1 \times l_0})$. A slight generalization of this is when one requires that $R^{1 \times l_2} X = \ker(R^{1 \times l_1} \xrightarrow{A} \text{coker}(L))$, where $L \in R^{a \times l_0}$ has the same number l_0 of columns as A . One then calls X a *syzygy matrix of A modulo L* , or *relative to the module $\text{coker}(L)$* .

So the rows of the matrix X of generating syzygies generate the solution space of the homogeneous linear system $\mathbf{x}A = 0 \pmod{L}$. For $\mathbf{z} \in R^{1 \times l_0}$ the statement $\mathbf{z} = 0 \pmod{L}$ means that there exists a $\mathbf{y} \in R^{1 \times a}$, such that $\mathbf{z} = \mathbf{y}L$.

3.2.1. ResolutionOfModule(M). By iterating the process of taking syzygies one obtains a free resolution of the module $M = \text{coker}(M)$:

$$\dots \xrightarrow{\varphi_{i+2}} R^{1 \times l_{i+1}} \xrightarrow{\varphi_{i+1}} R^{1 \times l_i} \xrightarrow{\varphi_i} R^{1 \times l_{i-1}} \xrightarrow{\varphi_{i-1}} \dots \xrightarrow{\varphi_2} R^{1 \times l_1} \xrightarrow{\varphi_1 = M} R^{1 \times l_0} \rightarrow M \rightarrow 0$$

of desired length. What `homalg` additionally does is the following: As explained in Section 2 we can assume the relation matrix (or the first syzygy matrix) $M = \varphi_1$ free of units. Starting from $i = 2$, whenever the i^{th} syzygy matrix φ_i is computed, `homalg` uses the units appearing in it to locate the redundant rows of the $(i-1)^{\text{st}}$ syzygy matrix φ_{i-1} . This means, if φ_i contains a unit in the j^{th} column, then the row in φ_i containing this unit says that the j^{th} row of φ_{i-1} is an R -linear combination of the other rows (of φ_{i-1}), so it is redundant for generating the $(i-1)^{\text{st}}$ syzygies and can be omitted from φ_{i-1} . The j^{th} row is thus deleted from φ_{i-1} and the i^{th} syzygy matrix φ_i is recomputed. The rows of the latter are again used to locate further redundant rows of φ_{i-1} . This process obviously stabilizes. Then one proceeds with the $(i+1)^{\text{st}}$ syzygy matrix φ_{i+1} , etc. We end up having a free resolution where all the matrices φ_i are free of units.

In the case of graded modules over a positively graded ring with degree 0 part a field, or modules over local rings, this process indeed yields a minimal free resolution (cf. [Eis95, p. 472] and [Sch03, p. 40]). In both cases eliminating units from the matrices φ_i of the resolution is equivalent to requiring that all entries belong to the unique maximal graded resp. unique maximal ideal of R .

However, and although in general this process does not yield a “minimal”⁸ free resolution, it often enough reduces the involved dimensions of the matrices considerably (cf. [KR05]).

⁸Such a notion is in general not even well defined, cf. [Eis95, p. 472].

3.2.2. SubfactorModule($\mathbf{M}_1, \mathbf{M}_2$). Given two matrices $\mathbf{M}_1$ and $\mathbf{M}_2$ with the same number of columns, computing a presentation matrix for the subfactor module $(\langle \mathbf{M}_1 \rangle + \langle \mathbf{M}_2 \rangle) / \langle \mathbf{M}_2 \rangle$ (short-hand: $\langle \mathbf{M}_1 \rangle / \langle \mathbf{M}_2 \rangle$) goes as follows: One computes a basis $\mathbf{B}$ of $\mathbf{M}_2$. Then one reduces $\mathbf{M}_1$ modulo $\mathbf{B}$ and gets $\mathbf{N}$. The syzygy matrix $\mathbf{S}$ of $\mathbf{M}$ modulo $\mathbf{N}$ is the desired presentation matrix.

4. CATEGORIES OF COMPLEXES OF GIVEN FINITE LENGTH

As always, let $\mathcal{C}$ be the module category of Section 2. By $D^k(\mathcal{C})$ we denote the category of chain complexes $C : C_k \rightarrow C_{k-1} \rightarrow \cdots \rightarrow C_1$ of $\mathcal{C}$ of finite length $k - 1$ and their chain maps.

Definition 4.1 (The category $D_i^k(\mathcal{C})$). For $i \in \{1, \dots, k\}$ let $D_i^k(\mathcal{C})$ be the factor category of $D^k(\mathcal{C})$ defined by forgetting in a chain map the morphisms between all but the i^{th} chain module.

Note that for a morphism in $D_i^k(\mathcal{C})$

$$\begin{array}{ccccccccc} C'_k & \longrightarrow & \cdots & \longrightarrow & C'_{i+1} & \longrightarrow & C'_i & \longrightarrow & C'_{i-1} & \longrightarrow & \cdots & \longrightarrow & C'_1 \\ & & & & & & \downarrow \varphi & & & & & & \\ C_k & \longrightarrow & \cdots & \longrightarrow & C_{i+1} & \longrightarrow & C_i & \longrightarrow & C_{i-1} & \longrightarrow & \cdots & \longrightarrow & C_1 \end{array}$$

there exists at least one commutative completion

$$\begin{array}{ccccccccc} C'_k & \longrightarrow & \cdots & \longrightarrow & C'_{i+1} & \longrightarrow & C'_i & \longrightarrow & C'_{i-1} & \longrightarrow & \cdots & \longrightarrow & C'_1 \\ \downarrow \varphi_k & & & & \downarrow \varphi_{i+1} & & \downarrow \varphi & & \downarrow \varphi_{i-1} & & & & \downarrow \varphi_1 \\ C_k & \longrightarrow & \cdots & \longrightarrow & C_{i+1} & \longrightarrow & C_i & \longrightarrow & C_{i-1} & \longrightarrow & \cdots & \longrightarrow & C_1 \end{array}$$

which is a preimage in $D^k(\mathcal{C})$.

By definition $D_1^1(\mathcal{C})$ is simply a different notation for $\mathcal{C}$. From now on all functors we consider take values in the module category $\mathcal{C}$.

Definition 4.2 (The functor Obj_i^k). Denote by $\text{Obj}_i^k : D_i^k(\mathcal{C}) \rightarrow \mathcal{C}$ the full functor mapping a complex to its i^{th} module:

$$\begin{array}{ccccccccc} C'_k & \longrightarrow & \cdots & \longrightarrow & C'_{i+1} & \longrightarrow & C'_i & \longrightarrow & C'_{i-1} & \longrightarrow & \cdots & \longrightarrow & C'_1 \\ & & & & & & \downarrow \varphi & & & & & & \\ C_k & \longrightarrow & \cdots & \longrightarrow & C_{i+1} & \longrightarrow & C_i & \longrightarrow & C_{i-1} & \longrightarrow & \cdots & \longrightarrow & C_1 \end{array} \quad \mapsto \quad \begin{array}{c} C'_i \\ \downarrow \varphi \\ C_i \end{array}$$

Definition 4.3 (The functor Mor_i^k). Denote by $\text{Mor}_i^k : D_i^k(\mathcal{C}) \rightarrow \mathcal{C}$ the full functor mapping a complex to its $(i + 1)^{\text{st}}$ morphism:

$$\begin{array}{ccccccccc} C'_k & \longrightarrow & \cdots & \longrightarrow & C'_{i+1} & \xrightarrow{\mu'_{i+1}} & C'_i & \longrightarrow & C'_{i-1} & \longrightarrow & \cdots & \longrightarrow & C'_1 \\ & & & & & & \downarrow \varphi & & & & & & \\ C_k & \longrightarrow & \cdots & \longrightarrow & C_{i+1} & \xrightarrow{\mu_{i+1}} & C_i & \longrightarrow & C_{i-1} & \longrightarrow & \cdots & \longrightarrow & C_1 \end{array} \quad \mapsto \quad \begin{array}{c} C'_{i+1} \xrightarrow{\mu'_{i+1}} C'_i \\ \downarrow \varphi \\ C_{i+1} \xrightarrow{\mu_{i+1}} C_i \end{array}$$

5. THE MORPHISM PART OF A FUNCTOR

A functor is by definition a map between two categories that maps objects to objects and, in a compatible way, morphisms to morphisms. To be allowed to speak about functors one needs to be able, not only to define the functor on objects, but also on morphisms between objects.

It might be puzzling for the reader that we start with a section devoted to the morphism part rather than the object part of functors. The reason for that will become clear towards the end of this section.

Here we write everything for covariant functors. Adapting things for contravariant functors is done in the obvious way.

For a morphism $S \xrightarrow{\varphi} T$ and a functor F we want to compute $F(\varphi)$. There are three cases `homalg` distinguishes:

- (Cmp) The functor F is defined in `homalg` as a composition of two functors: $F = F_1 \circ F_2$.
- (Der) The functor F is defined in `homalg` as the i^{th} (left) derivation⁹ of another functor: $F = L_i G$.
- (Bsc) The functor F is defined in `homalg` neither by composition nor by derivation. In what follows such functors are called `homalg-basic`¹⁰ functors.

Dealing with (Cmp), i.e. with a composed functor is easy: Since $F(\varphi) = F_1(F_2(\varphi))$ one is able to reduce computing $F(\varphi)$ to computing $F_2(\varphi)$ and then $F_1(F_2(\varphi))$. A bit more involved is the case (Der), i.e. when $F = L_i G$. In Subsection 7.2 it is shown how to reduce the computation of $F(\varphi)$ to essentially computing $G(\varphi)$. For `homalg-basic` functors the idea is to reduce the computation of $F(\varphi)$ to completing an image square (cf. 3.1.2, case (2)). To this end one *embeds* $F(S)$ resp. $F(T)$ in a module $\text{Hull}_F(S)$ resp. $\text{Hull}_F(T)$ with an induced morphism $\text{Hull}_F(\varphi)$ determined by φ :

$$\begin{array}{ccc}
 0 & \longrightarrow & F(S) \xrightarrow{\iota_F(S)} \text{Hull}_F(S) \\
 & & \downarrow F(\varphi) \qquad \downarrow \text{Hull}_F(\varphi) \\
 0 & \longrightarrow & F(T) \xrightarrow{\iota_F(T)} \text{Hull}_F(T)
 \end{array}$$

Expressed categorically, Hull_F is a functor, which we call a *hull functor* of F , and ι_F is a natural transformation, which we call the *corresponding natural embedding*.

For a given functor F the idea is to either define the hull functor Hull_F from scratch (e.g. for¹¹ `Cokernel` (in 6.1.1), `Hom_R` (in 6.2.1), `TensorProduct` (in 6.2.2) and `Hom` (in 6.2.3)) or

⁹`homalg` provides procedures to left derive covariant functors and right derive contravariant functors. These are the cases computed via a projective resolution of the module.

¹⁰The prefix `homalg` indicates that the notion of “basic functor” is *not* a mathematical definition. If, for example, the functor $\text{Hom}_R(\text{Hom}_R(-, R), R)$ would have been implemented without using `homalg`’s composition procedure `ComposeFunctors` (see B.4), we then would call it `homalg-basic`.

¹¹Since one can directly provide the action of `Cokernel` and `TensorProduct` on morphisms, one takes them as their own hull functors.

to define Hull_F by composition of already defined functors and the forgetful functors Obj_i^k (Def. 4.2) and Mor_j^l (Def. 4.3) (e.g. for Kernel (in 6.1.2) and DefectOfHoms (in 6.1.3)).

The procedure in `homalg` that precisely accomplishes the above mentioned distinction is called `FunctorMap` (cf. Appendix B.7).

6. SOME `homalg`-BASIC FUNCTORS

Since we need to explain how to construct for each functor its hull functor, we need to first of all mention which specific standard method for computing the object part we use (see for example [GP02]) and then how to construct the hull functor in the specific setup. The hull functor is the missing piece of data that allows one to automatically compute the functor part on morphisms.

All functors we consider are of the form $F : D_i^k(\mathcal{C}) \rightarrow \mathcal{C}$. We simply distinguish two types of functors, depending on whether $F(C)$ is a subfactor module of $\text{Obj}_i^k(C)$, for all objects $C \in D_i^k(\mathcal{C})$, or not. In what follows a functor of the previous kind is called a *functor producing subfactor modules*.

To avoid confusing the two parts of a functor with source category¹² $D_k^2(\mathcal{C})$ (which has as its set of objects also morphisms between modules), we use two different names for the two parts: If the object part of a functor is called F , then its morphism part is called $F\text{Map}$. The name F is also used to refer to the functor in both its parts.

6.1. Functors producing subfactor modules.

6.1.1. *The functor `Cokernel`.* On the level of objects the covariant cokernel functor associates to a morphism between two modules its cokernel. $\text{Cokernel} : D_1^2(\mathcal{C}) \rightarrow \mathcal{C}$, i.e.

$$\begin{array}{ccc} A' \xrightarrow{\alpha} A & & \text{Cokernel}(\alpha) \\ \varphi \downarrow & \mapsto & \downarrow \text{CokernelMap}(\varphi) \\ B' \xrightarrow{\beta} B & & \text{Cokernel}(\beta) \end{array}$$

such that

$$\begin{array}{ccccccc} A' & \xrightarrow{\alpha} & A & \longrightarrow & \text{Cokernel}(\alpha) & \longrightarrow & 0 \\ & & \varphi \downarrow & & \downarrow \text{CokernelMap}(\varphi) & & \\ B' & \xrightarrow{\beta} & B & \longrightarrow & \text{Cokernel}(\beta) & \longrightarrow & 0 \end{array}$$

is commutative and exact.

Defining the object part $\text{Cokernel}(\alpha)$ is simple: After fixing a presentation matrix A for A and generators for A' one can view α as a matrix with the same number of columns as A . Now take the supermatrix $\begin{pmatrix} \alpha \\ A \end{pmatrix}$ as a presentation matrix for $\text{Cokernel}(\alpha)$.

The cokernel functor is the most basic functor in our setting, in the sense that computing its morphism part $\text{CokernelMap}(\varphi)$ is trivial: If we take the residue classes of the generators of A resp. B to be the generators of $\text{Cokernel}(\alpha)$ resp. $\text{Cokernel}(\beta)$, then

¹²This is the case in 6.1.1, 6.1.2.

the matrix representing $\text{CokernelMap}(\varphi)$ coincides with that of φ . Hence one can set the hull functor $\text{Hull}_{\text{Cokernel}} = \text{Cokernel}$ and the natural embedding ι_{Cokernel} is the identity transformation¹³.

6.1.2. *The functor Kernel*. On the level of objects the covariant kernel functor associates to a morphism between two modules its kernel. $\text{Kernel} : D_2^2(\mathcal{C}) \rightarrow \mathcal{C}$, i.e.

$$\begin{array}{ccc} A \xrightarrow{\alpha} A'' & & \text{Kernel}(\alpha) \\ \downarrow \varphi & \mapsto & \downarrow \text{KernelMap}(\varphi) \\ B \xrightarrow{\beta} B'' & & \text{Kernel}(\beta) \end{array}$$

such that

$$\begin{array}{ccccccc} 0 & \longrightarrow & \text{Kernel}(\alpha) & \longrightarrow & A & \xrightarrow{\alpha} & A'' \\ & & \downarrow \text{KernelMap}(\varphi) & & \downarrow \varphi & & \\ 0 & \longrightarrow & \text{Kernel}(\beta) & \longrightarrow & B & \xrightarrow{\beta} & B'' \end{array}$$

is commutative and exact.

Defining the object part $\text{Kernel}(\alpha)$ goes like this: After fixing a presentation matrix A resp. A'' for A resp. A'' one can view α as a matrix with the same number of columns as A'' . Compute the syzygy matrix iota of α modulo A'' (cf. the beginning of Subsection 3.2). Now use SubfactorModule to compute $\text{Kernel}(\alpha) := \langle \text{iota} \rangle / \langle A \rangle$ (cf. 3.2.2). See also [GP02, p. 97].

In the case of the functor Kernel the hull functor is obviously $\text{Hull}_{\text{Kernel}} = \text{Obj}_2^2$ and the natural embedding ι_{Kernel} is the transformation embedding the kernel of a morphism into its source module:

$$0 \longrightarrow \text{Kernel}(\alpha) \xrightarrow{\iota_{\text{Kernel}}(\alpha)} A = \text{Obj}_2^2(A \xrightarrow{\alpha} A'')$$

The matrix of the natural embedding is simply iota .

6.1.3. *The functor DefectOfHoms*. On the level of objects the covariant defect functor associates to two composable morphisms α_1 and α_2 with $\alpha_2\alpha_1 = 0$ their defect of exactness $\ker(\alpha_2)/\text{im}(\alpha_1)$. $\text{DefectOfHoms} : D_2^3(\mathcal{C}) \rightarrow \mathcal{C}$, i.e.

$$\begin{array}{ccc} A' \xrightarrow{\alpha_1} A \xrightarrow{\alpha_2} A'' & & \text{DefectOfHoms}(\alpha_1, \alpha_2) \\ \downarrow \varphi & \mapsto & \downarrow \text{DefectOfHomsMap}(\varphi) \\ B' \xrightarrow{\beta_1} B \xrightarrow{\beta_2} B'' & & \text{DefectOfHoms}(\beta_1, \beta_2) \end{array}$$

¹³This is not the whole truth. The functor Cokernel calls a procedure named **Presentation**, which, among other things, tries with the help of the procedure **BetterGenerators**, to reduce the number of generators of the resulting module using either normal form algorithms referred to in the introduction and at the end of Appendix A, in case they are available and applicable, or otherwise, beside the one described in Section 2, several clever heuristics. Taking care of this, is a simple, but technical issue.

such that

$$\begin{array}{ccccc} 0 & \longrightarrow & \text{DefectOfHoms}(\alpha_1, \alpha_2) & \longrightarrow & \text{Cokernel}(\alpha_1) \xrightarrow{\alpha_2} A'' \\ & & \downarrow \text{DefectOfHomsMap}(\varphi) & & \downarrow \text{CokernelMap}(\varphi) \\ 0 & \longrightarrow & \text{DefectOfHoms}(\beta_1, \beta_2) & \longrightarrow & \text{Cokernel}(\beta_1) \xrightarrow{\beta_2} B'' \end{array}$$

is commutative and exact.

The definition of the object part of `DefectOfHoms` uses the ideas in 6.1.1 and 6.1.2: Fix a presentation matrix A for A' and A'' for A'' . Fix generators for A' . Then one can view α_1 resp. α_2 as a matrix with the same number of columns as A resp. A'' . Using A , α_2 and A'' compute the matrix `iota` of the embedding of $\text{Kernel}(\alpha_2)$ in A as in 6.1.2. Then use `SubfactorModule` to compute the defect $\text{DefectOfHoms}(\alpha_1, \alpha_2) := \langle \text{iota} \rangle / \left\langle \begin{pmatrix} \alpha_1 \\ A \end{pmatrix} \right\rangle$.

In the case of the functor `DefectOfHoms` the hull functor is obviously $\text{Hull}_{\text{DefectOfHoms}} = \text{Cokernel} \circ \text{Mor}_2^3$ and the natural embedding $\iota_{\text{DefectOfHoms}}$ is the transformation embedding the defect of two composable morphisms into the cokernel of the first morphism:

$$0 \longrightarrow \text{DefectOfHoms}(\alpha_1, \alpha_2) \xrightarrow{\iota_{\text{DefectOfHoms}}(\alpha_1, \alpha_2)} \text{Cokernel}(\alpha_1),$$

where $\text{Cokernel}(\alpha_1) = \text{Cokernel}(\text{Mor}_2^3(A' \xrightarrow{\alpha_1} A \xrightarrow{\alpha_2} A''))$. The matrix of the natural embedding is `iota`.

The functors `Cokernel` and `Kernel` are obviously special cases of this functor.

6.2. Other types of homalg-basic functors. Contrary to functors producing subfactor modules, where the morphism part of the hull functor is given by the induced morphism on the factor module, here we need to explicitly mention how the morphism part of the hull functor is defined.

For the rest of the subsection let

$$M = \text{coker}(\mathbf{M}) = R^{1 \times l_0} / R^{1 \times l_1} \mathbf{M}, \quad L = \text{coker}(\mathbf{L}) = R^{1 \times l'_0} / R^{1 \times l'_1} \mathbf{L},$$

be two finitely presented modules:

$$R^{1 \times l_1} \xrightarrow{\mathbf{M}} R^{1 \times l_0} \xrightarrow{\nu_M} M \longrightarrow 0, \quad R^{1 \times l'_1} \xrightarrow{\mathbf{L}} R^{1 \times l'_0} \xrightarrow{\nu_L} L \longrightarrow 0.$$

Further let $M \xrightarrow{\varphi} N$ be a morphism, between two finitely presented modules M and

$$N = \text{coker}(\mathbf{N}) = R^{1 \times l''_0} / R^{1 \times l''_1} \mathbf{N},$$

i.e.

$$\varphi \in R^{l_0 \times l''_0}.$$

Note that we write the morphisms on the right, i.e. we use the row convention.

6.2.1. *The functor $\text{Hom}_{\mathbf{R}}$.* Let R be a (not necessarily commutative) ring with a fixed involution¹⁴ θ . For a right R -module H , define the left R -module H^θ by setting $H^\theta = H$ as abelian groups and $r \cdot h := h\theta(r)$ for all $r \in R$ and $h \in H$. So the involution θ allows one to rewrite any right R -module H as a left R -module H^θ .

Recall that $\text{Hom}_R(-, R)$ is a contravariant functor from the category of left R -modules to the category of right R -modules. We use the involution θ to transform the resulting right R -module into a left R -module. We call the resulting functor $\text{Hom}_R^\theta(-, R)$. The idea is to reduce the computation of the homomorphism module to computing a kernel. Since $\text{Hom}_R(-, R)$ is left exact, one obtains the exact sequence of right R -modules:

$$0 \longrightarrow \text{Hom}_R(M, R) \xrightarrow{\nu_M^*} \text{Hom}_R(R^{1 \times l_0}, R) \xrightarrow{\mathbf{M}^\cdot} \text{Hom}_R(R^{1 \times l_1}, R).$$

We compute $\text{Hom}_R(M, R)$ as the kernel of the right most morphism. Following the row convention we identify $\text{Hom}_R(R^{1 \times j}, R)$ with $R^{j \times 1}$, which justifies the notation $(\mathbf{M}^\cdot)$ for the right most morphism. Applying θ yields the exact sequence of left R -modules:

$$0 \longrightarrow \text{Hom}_R^\theta(M, R) \xrightarrow{\nu_M^*} R^{1 \times l_0} \xrightarrow{\mathbf{M}^\theta} R^{1 \times l_1},$$

where $(\mathbf{M}^\theta)_{ab} = \theta(\mathbf{M}_{ba})$ and $(R^{l \times 1})^\theta = R^{1 \times l}$. Thus set

$$\text{Hom}_{\mathbf{R}}(M) := \text{Kernel}(R^{1 \times l_0} \xrightarrow{\mathbf{M}^\theta} R^{1 \times l_1}).$$

This definition proposes setting $\text{Hull}_{\text{Hom}_{\mathbf{R}}}(M) := R^{1 \times l_0}$ and taking the embedding of the kernel $\text{Hom}_{\mathbf{R}}(M)$ in $R^{1 \times l_0}$ as the natural embedding (cf. 6.1.2). The morphism part of the hull functor is hence defined by $\text{Hull}_{\text{Hom}_{\mathbf{R}}}(\varphi) := \varphi^\theta$:

$$\begin{array}{ccc} 0 & \longrightarrow & \text{Hom}_{\mathbf{R}}(M) \longrightarrow R^{1 \times l_0} = (R^{l_0 \times 1})^\theta \\ & \uparrow \text{HomMap}_{\mathbf{R}}(\varphi) & \uparrow \varphi^\theta \\ 0 & \longrightarrow & \text{Hom}_{\mathbf{R}}(N) \longrightarrow R^{1 \times l_0''} = (R^{l_0'' \times 1})^\theta, \end{array}$$

where $\varphi^\theta : R^{1 \times l_0} \rightarrow R^{1 \times l_0''}$ is a morphism of free *left* modules.

Although the definition of $\text{Hull}_{\text{Hom}_{\mathbf{R}}}(M)$ depends on the presentation of M , it is nevertheless functorial because of the equivalence of the categories $\mathcal{C}^{\text{mod}}$ and $\mathcal{C}^{\text{mat}}$.

$\text{Hom}_{\mathbf{R}}$ is a contravariant functor. The transposition in the definition of $\mathbf{M}^\theta$ (and φ^θ) is the manifestation of this contravariance.

6.2.2. *The functor TensorProduct .* Let R be a commutative¹⁵ ring. Recall that $-\otimes_R-$ is a bifunctor, covariant in both arguments. The idea is to reduce the computation of the tensor product module to computing a cokernel. Since $-\otimes_R-$ is right exact in both arguments, the tensor product of the two presentations $R^{1 \times l_1} \xrightarrow{\mathbf{M}} R^{1 \times l_0}$ of M and $R^{1 \times l_1'} \xrightarrow{\mathbf{L}} R^{1 \times l_0'}$ of L

¹⁴An order 2 anti-automorphism: $\theta^2 = \text{id}_R$ and $\theta(ab) = \theta(b)\theta(a)$ for all $a, b \in R$.

¹⁵Cf. Subsection 6.2.4.

(each regarded as a two term complex) is a presentation of $M \otimes_R L$ (cf. [GP02, Section 2.7]):

$$(R^{1 \times l_1} \otimes_R R^{1 \times l'_0}) \oplus_R (R^{1 \times l_0} \otimes_R R^{1 \times l'_1}) \xrightarrow{(\tau)} R^{1 \times l_0} \otimes_R R^{1 \times l'_0} \xrightarrow{\nu_{M \otimes_R L}} M \otimes_R L \longrightarrow 0.$$

We compute $M \otimes_R L$ as the cokernel of τ . After identifying $R^{1 \times j} \otimes_R R^{1 \times k}$ with $R^{1 \times jk}$ the morphism τ is given by the matrix $T = \begin{pmatrix} M \otimes I_{l'_0} \\ I_{l_0} \otimes L \end{pmatrix}$, where $\otimes$ is the KRONECKER product of matrices and I_{l_0} resp. $I_{l'_0}$ is the identity matrix on M resp. L .

Our convention in defining the KRONECKER product of two matrices $A = (a_{ij})$ and B is the usual one: $A \otimes B := (a_{ij}B)$.

We define

$$\text{TensorProduct}(M, L) := \text{Cokernel}(R^{1 \times (l_1 l'_0 + l_0 l'_1)} \xrightarrow{T} R^{1 \times l_0 l'_0}).$$

Define the morphism part of the functor $\text{TensorProduct}(-, L)$ to be the KRONECKER product

$$\text{TensorProduct}(\varphi, L) := \varphi \otimes I_{l'_0}.$$

Here the hull functor $\text{Hull}_{\text{TensorProduct}(-, L)}$ coincides with the functor and the natural embedding is the identity transformation.

Analogously for the functor $\text{TensorProduct}(L, -)$ define

$$\text{TensorProduct}(L, \varphi) := I_{l'_0} \otimes \varphi.$$

Again, the hull functor $\text{Hull}_{\text{TensorProduct}(-, L)}$ coincides with the functor and the natural embedding is the identity transformation.

$\text{TensorProduct}(-, -)$ is a bifunctor, covariant in each argument.

6.2.3. The functor Hom . Let R be a *commutative*¹⁶ ring. Recall that $\text{Hom}_R(-, -)$ is a bifunctor, contravariant in its first argument and covariant in the second. The idea is to reduce the computation of the homomorphism module to computing a kernel. Since $\text{Hom}_R(-, L)$ is left exact for any module L and $\text{Hom}_R(P, -)$ is exact for P projective (or free) one obtains (cf. [GP02, p. 104]):

$$\begin{array}{ccccccc} & & & 0 & & & 0 \\ & & & \uparrow & & & \uparrow \\ 0 & \longrightarrow & \text{Hom}_R(M, L) & \xrightarrow{\nu_M^*} & \text{Hom}_R(R^{1 \times l_0}, L) & \xrightarrow{(\kappa)} & \text{Hom}_R(R^{1 \times l_1}, L) \\ & & \uparrow \nu_L & & \uparrow \nu_L & & \uparrow \nu_L \\ 0 & \longrightarrow & \text{Hom}_R(M, R^{1 \times l'_0}) & \xrightarrow{\nu_M^*} & \text{Hom}_R(R^{1 \times l_0}, R^{1 \times l'_0}) & \xrightarrow{M \cdot} & \text{Hom}_R(R^{1 \times l_1}, R^{1 \times l'_0}) \\ & & \uparrow & & \uparrow \cdot L & & \uparrow \cdot L \\ 0 & \longrightarrow & \text{Hom}_R(M, R^{1 \times l'_1}) & \xrightarrow{\nu_M^*} & \text{Hom}_R(R^{1 \times l_0}, R^{1 \times l'_1}) & \xrightarrow{M \cdot} & \text{Hom}_R(R^{1 \times l_1}, R^{1 \times l'_1}). \end{array}$$

We compute $\text{Hom}_R(M, L)$ as the kernel of κ in the first row. Identifying $\text{Hom}_R(R^{1 \times j}, R^{1 \times k})$ with $R^{j \times k}$ justifies the notation used for the morphisms of the lower right square of the

¹⁶Cf. Subsection 6.2.4.

above diagram. Further, identifying $R^{j \times k}$ with $R^{1 \times jk}$ (by writing all the j rows as one long row) gives rise to the identification¹⁷ of $\text{Hom}_R(R^{1 \times l_0}, L)$ with $\text{Cokernel}(I_{l_0} \otimes L)$ and of $\text{Hom}_R(R^{1 \times l_1}, L)$ with $\text{Cokernel}(I_{l_1} \otimes L)$. The induced morphism

$$\kappa : \text{Hom}_R(R^{1 \times l_0}, L) \rightarrow \text{Hom}_R(R^{1 \times l_1}, L)$$

is then given by the matrix $(M \otimes I_{l'_0})^{\text{tr}}$. Thus define

$$\text{Hom}(M, L) := \text{Kernel}(\text{Cokernel}(I_{l_0} \otimes L) \xrightarrow{(M \otimes I_{l'_0})^{\text{tr}}} \text{Cokernel}(I_{l_1} \otimes L)).$$

This definition proposes setting $\text{Hull}_{\text{Hom}(-, L)}(M) := \text{Cokernel}(I_{l_0} \otimes L)$ and taking the embedding of the kernel $\text{Hom}(M, L)$ in $\text{Cokernel}(I_{l_0} \otimes L)$ as the natural embedding (cf. 6.1.2). The morphism part of the hull functor is hence defined by $\text{Hull}_{\text{Hom}(-, L)}(\varphi) := (\varphi \otimes I_{l'_0})^{\text{tr}}$:

$$\begin{array}{ccccc} 0 & \longrightarrow & \text{Hom}(M, L) & \longrightarrow & \text{Cokernel}(I_{l_0} \otimes L) \\ & & \text{HomMap}(\varphi) \uparrow & & \uparrow (\varphi \otimes I_{l'_0})^{\text{tr}} \\ 0 & \longrightarrow & \text{Hom}(N, L) & \longrightarrow & \text{Cokernel}(I_{l'_0} \otimes L). \end{array}$$

To address the functoriality of $\text{Hom}(-, -)$ in the second argument, interchange the role of M and L , and set $\text{Hull}_{\text{Hom}(L, -)}(M) := \text{Cokernel}(I_{l'_0} \otimes M)$ and $\text{Hull}_{\text{Hom}(L, -)}(\varphi) := I_{l'_0} \otimes \varphi$:

$$\begin{array}{ccccc} 0 & \longrightarrow & \text{Hom}(M, L) & \longrightarrow & \text{Cokernel}(I_{l'_0} \otimes M) \\ & & \text{Hom2Map}(\varphi) \downarrow & & \downarrow I_{l'_0} \otimes \varphi \\ 0 & \longrightarrow & \text{Hom}(N, L) & \longrightarrow & \text{Cokernel}(I_{l'_0} \otimes N). \end{array}$$

$\text{Hom}(-, -)$ is a bifunctor, contravariant in its first and covariant in its second argument. Transposing the matrix $M \otimes I_{l'_0}$ (and $\varphi \otimes I_{l'_0}$) is the manifestation of the contravariance in the first argument.

6.2.4. One last word on the commutativity of the ring R . For the most general definition of tensor product of modules one starts with a not necessarily commutative ring R , a right R -module M_R , and a left R -module ${}_R N$. If the R -module structure of M resp. N comes from a (Q, R) -bimodule resp. an (R, S) -bimodule structure, then their tensor product over R is in a natural way a (Q, S) -bimodule ${}_Q M_R \otimes_R {}_R N_S$. Q and S , again, are not necessarily commutative rings. Analogously, let M and N be two left modules over a not necessarily commutative ring R and denote by $\text{Hom}_R({}_R M, {}_R N)$ the abelian group of R -homomorphisms. If the R -module structure of M resp. N comes from an (R, Q) -bimodule resp. an (R, S) -bimodule structure, then $\text{Hom}_R({}_R M, {}_R N)$ is again in a natural way a (Q, S) -bimodule.

Note that in both cases the resulting module might not be finitely generated as a (Q, S) -bimodule, even if M and N are finitely generated as R -modules.

¹⁷ $R^{j \times l'_1} \xrightarrow{\cdot L} R^{j \times l'_0}$ becomes $R^{1 \times j l'_1} \xrightarrow{I_j \otimes L} R^{1 \times j l'_0}$, and $R^{l_0 \times k} \xrightarrow{M} R^{l_1 \times k}$ becomes $R^{1 \times l_0 k} \xrightarrow{(M \otimes I_k)^{\text{tr}}} R^{1 \times l_1 k}$.

In the special case where either M or N is an (R, R) -bimodule, then $M \otimes_R N$ resp. $\text{Hom}_R(M, N)$ is again an R -module¹⁸. This is always the case when the ring is commutative, since then every R -module is an (R, R) -bimodule in the obvious way.

The **Maple** implementation of **homalg** does neither support changing the ring, nor bimodule structures. These are issues we want to address in future implementations. But even though, the above mentioned problem of non-finite generation will remain the major obstacle.

7. DERIVED FUNCTORS

The philosophy of derived categories is, roughly speaking, to replace a module by one of its resolutions, and then to look at the resolution as a very special type of complexes, with homology concentrated at degree 0. After inverting quasi-isomorphisms, one obtains the derived category, where the objects are quasi-isomorphism types of complexes. Especially, all resolutions of a module become isomorphic objects in the derived category.

Using the cylinder-cone-translation construction [GM03, III.3] one constructs out of every short exact sequence of complexes, a so called *distinguished triangle*. By passing to homology we again obtain distinguished triangles in the category of graded objects (which one can view as cyclic complexes, i.e. complexes with zero boundary maps [GM03, III.2.3]). A popular way to start, is to take a distinguished triangle coming from a short exact sequence of complexes that are simultaneously resolving a short exact sequence of modules. Then one applies a functor, that turns such distinguished triangles again into distinguished triangles, and at last one takes the homology. The classical way of writing such a distinguished triangle of homologies is as a *long exact homology sequence*.

The reason for recalling the standard definitions in the following subsections is not only to indicate how they are computed using **homalg**, but to finish the discussion of Section 5. This is done in Subsection 7.2.

7.1. The procedure ResolveModule: Resolve a module. By resolving a module M , which we view as a complex concentrated in degree 0, we obtain a complex of free (resp. projective) modules and a quasi-isomorphism

$$\begin{array}{ccccccc} \cdots & \longrightarrow & P_2 & \longrightarrow & P_1 & \longrightarrow & P_0 \longrightarrow 0 \\ & & \downarrow & & \downarrow & & \downarrow \\ \cdots & \longrightarrow & 0 & \longrightarrow & 0 & \longrightarrow & M \longrightarrow 0. \end{array}$$

After inverting quasi-isomorphisms all resolutions become isomorphic.

For an additive functor F and a module M with a resolution

$$P : P_{q+1} \longrightarrow P_q \longrightarrow P_{q-1} \longrightarrow \cdots \longrightarrow P_1 \longrightarrow P_0 \longrightarrow 0$$

define the q^{th} derived functor $L_q F$ applied to M by setting $L_q F(M) := H_q(F(P))$, the defect of the two consecutive morphisms $F(P_{q+1}) \rightarrow F(P_q)$ and $F(P_q) \rightarrow F(P_{q-1})$ (cf. 6.1.3 DefectOfHoms).

¹⁸In theory, this special case could work in **homalg**, and indeed it does for very special cases, of course, beside the trivial case when $M = R$ or $N = R$.

There is a cheaper method to compute the left derivation of a *right exact* covariant functor, which is based on [HS97, the definition of $\tilde{L}_q$ in IV.(10.1), p. 156 and Prop. IV.5.5, p. 133] and uses `Kernel` instead of `DefectOfHoms`. By duality, there is a cheaper method to compute the right derivation of a *left exact* contravariant functor, which is based on [HS97, Prop. IV.5.8] and uses `Cokernel` instead of `DefectOfHoms`. Both methods are implemented in `homalg`.

7.2. The procedure `ResolutionOfSeq`: Resolve a morphism. Given a morphism $M \xrightarrow{\varphi} N$ one resolves M and N freely

$$\begin{array}{ccccccccccc} \text{(Lift)} & P_{q+1} & \longrightarrow & P_q & \longrightarrow & P_{q-1} & \longrightarrow & \cdots & \longrightarrow & P_1 & \longrightarrow & P_0 & \longrightarrow & M & \longrightarrow & 0 \\ & & & \downarrow \varphi_q & & \downarrow \varphi_{q-1} & & & & \downarrow \varphi_1 & & \downarrow \varphi_0 & & \downarrow \varphi & & \\ & P'_{q+1} & \longrightarrow & P'_q & \longrightarrow & P'_{q-1} & \longrightarrow & \cdots & \longrightarrow & P'_1 & \longrightarrow & P'_0 & \longrightarrow & N & \longrightarrow & 0, \end{array}$$

and computes the φ_q 's by iteratively completing image squares. Here one needs a free resolution of M to be in case (2) of `CompleteImSq`, 3.1.2. Applying F one gets $F(P_q) \xrightarrow{F(\varphi_q)} F(P'_q)$. But now the object part of the functor $L_q F$ applied to M (resp. N) is a subfactor module of $F(P_q)$ (resp. $F(P'_q)$) and one is in the situation of `DefectOfHoms`, 6.1.3. This is all what `FunctorMap` needs to compute the morphism part of a derived functor. This finishes the discussion of Section 5.

7.3. The procedure `ResolveShortExactSeq`: Resolving a short exact sequence of modules. To resolve a short exact sequence of modules $0 \rightarrow M' \rightarrow M \rightarrow M'' \rightarrow 0$, one starts with a resolution of M'' :

$$\begin{array}{ccccccc} & & & & & 0 & \\ & & & & & \downarrow & \\ & & & & & M' & \longrightarrow 0 \\ & & & & & \downarrow & \\ & & & & & M & \longrightarrow 0 \\ & & & & & \downarrow & \\ \cdots & \longrightarrow & P''_2 & \longrightarrow & P''_1 & \longrightarrow & P''_0 & \longrightarrow & M'' & \longrightarrow 0. \\ & & \downarrow & & \downarrow & & \downarrow & & \downarrow & \\ & & 0 & & 0 & & 0 & & 0 & \end{array}$$

Then one completes the middle line by taking free hulls of iterated pullbacks. Finally one fills the upper line by taking kernels to obtain:

$$\begin{array}{ccccccc} \text{(M)} & & & & & 0 & & 0 & & 0 & & 0 \\ & & & & & \downarrow & & \downarrow & & \downarrow & & \downarrow \\ \cdots & \longrightarrow & P'_2 & \longrightarrow & P'_1 & \longrightarrow & P'_0 & \longrightarrow & M' & \longrightarrow & 0 \\ & & \downarrow & & \downarrow & & \downarrow & & \downarrow & & \\ \cdots & \longrightarrow & P_2 & \longrightarrow & P_1 & \longrightarrow & P_0 & \longrightarrow & M & \longrightarrow & 0 \\ & & \downarrow & & \downarrow & & \downarrow & & \downarrow & & \\ \cdots & \longrightarrow & P''_2 & \longrightarrow & P''_1 & \longrightarrow & P''_0 & \longrightarrow & M'' & \longrightarrow & 0, \\ & & \downarrow & & \downarrow & & \downarrow & & \downarrow & & \\ & & 0 & & 0 & & 0 & & 0 & & \end{array}$$

with exact columns and rows. This method is implemented in the procedure **ResolveShortExactSeq**. There are several other methods to resolve a short exact sequence simultaneously, cf. [HS97, Proof of Theorem IV.6.1].

Computing the pullback A' of $B' \xrightarrow{\beta} B \xleftarrow{\varphi} A$ is reduced to computing a kernel, namely that of $A \oplus B' \xrightarrow{\begin{pmatrix} \varphi \\ -\beta \end{pmatrix}} B$. The two maps $B' \xleftarrow{\psi} A' \xrightarrow{\alpha} A$ of the pullback are the two parts of the kernel embedding $0 \rightarrow A' \xrightarrow{\begin{pmatrix} \alpha & \psi \end{pmatrix}} A \oplus B'$ (cf. 6.1.2).

7.4. The procedure LongExactHomologySeq: Connecting homomorphism and long exact sequences. Applying an additive covariant functor F to the truncation of the diagram (M)

$$(P) \quad \begin{array}{ccccccc} & & 0 & & 0 & & 0 \\ & & \downarrow & & \downarrow & & \downarrow \\ \cdots & \longrightarrow & P'_2 & \longrightarrow & P'_1 & \longrightarrow & P'_0 \longrightarrow 0 \\ & & \downarrow & & \downarrow & & \downarrow \\ \cdots & \longrightarrow & P_2 & \longrightarrow & P_1 & \longrightarrow & P_0 \longrightarrow 0 \\ & & \downarrow & & \downarrow & & \downarrow \\ \cdots & \longrightarrow & P''_2 & \longrightarrow & P''_1 & \longrightarrow & P''_0 \longrightarrow 0 \\ & & \downarrow & & \downarrow & & \downarrow \\ & & 0 & & 0 & & 0 \end{array}$$

results in a diagram $\overline{P} = F(P)$ where the columns are still exact, but where the rows are now in positive degrees, in general, no longer exact. Connecting the homologies of the rows one obtains the *long exact homology sequence*

$$\cdots \xrightarrow{\partial_{q+1}} L_q F(M') \rightarrow L_q F(M) \rightarrow L_q F(M'') \xrightarrow{\partial_q} L_{q-1} F(M') \rightarrow \cdots,$$

where the *connecting homomorphisms* are computed via the snake lemma applied to the diagrams

$$\begin{array}{ccc} & & 0 \\ & & \downarrow \\ \overline{P}'_{q+1}/\overline{B}'_{q+1} & \longrightarrow & \overline{Z}'_q \\ \downarrow & & \downarrow \\ \overline{P}_{q+1}/\overline{B}_{q+1} & \longrightarrow & \overline{Z}_q \\ \downarrow & & \downarrow \\ \overline{P}''_{q+1}/\overline{B}''_{q+1} & \longrightarrow & \overline{Z}''_q \\ \downarrow & & \\ 0 & & \end{array}$$

by taking kernels and cokernels, where $\overline{B}_i := \text{im}(\overline{P}_{i+1} \rightarrow \overline{P}_i)$ and $\overline{Z}_i := \text{ker}(\overline{P}_i \rightarrow \overline{P}_{i-1})$. One computes the connecting homomorphism from $\text{ker}(\overline{P}''_{q+1}/\overline{B}''_{q+1} \rightarrow \overline{Z}''_q)$ to $\text{coker}(\overline{P}'_{q+1}/\overline{B}'_{q+1} \rightarrow \overline{Z}'_q)$ by a diagram chase, which accounts in taking preimages twice,

namely under the maps $\overline{P}_{q+1}/\overline{B}_{q+1} \rightarrow \overline{P}_{q+1}''/\overline{B}_{q+1}''$ and $\overline{Z}'_q \rightarrow \overline{Z}_q$. For this the procedure `Preimage` from 3.1.4 is used.

Applying a contravariant functor to (P) yields a *long exact cohomology sequence*. The corresponding procedure is called `LongExactCohomologySeq`.

APPENDIX A. THE RING PACKAGES

The following `Maple` ring packages have successfully been used with `homalg`. In each of the following descriptions we append a list of rings which can be dealt with in `homalg` using the respective package. Further, and without any extra help from the ring package, `homalg` can automatically compute over residue class rings of any supported ring.

- `PIR` [Bar07] is one more tiny package, or rather a pseudo-package, that makes `Maple`'s built-in facilities for dealing with integers and some other principal ideal rings available to `homalg`. (Prime subfields $\mathbb{Q}$ and $\mathbb{Z}/p\mathbb{Z}$ and their finite field extensions, realized as primitive extensions, rational function fields over the previous fields, the integers $\mathbb{Z}$, the GAUSSIAN integers $\mathbb{Z}[\sqrt{-1}]$ and univariate polynomial rings $\mathbb{Z}/p\mathbb{Z}[x]$, where p is a prime, $\mathbb{Q}[x]$ and $K[x]$, where K is a rational function field over a finite extension of $\mathbb{Q}$, realized as a primitive extension.)
- `Involutive` [BCG⁺03] implements the involutive basis technique of V. P. GERDT and Y. A. BLINKOV in `Maple`. An involutive basis is a special kind of GRÖBNER basis for an ideal of a polynomial ring or, more generally, for a submodule of a free module over a polynomial ring. Involutive bases have nice combinatorial properties [PR05], and the algorithms designed by V. P. GERDT and Y. A. BLINKOV [Ger05, GB98a, GB98b] compute them efficiently. In fact, these algorithms provide an efficient alternative to BUCHBERGER's algorithm [Buc06] to compute GRÖBNER bases. `Involutive` restricts to particular involutive bases, namely JANET bases. It also provides an interface to a C++ implementation of the involutive basis technique which can be used to call the fast routines when needed as well as to switch to these fast routines for the whole `Maple` session. (Commutative polynomial rings: $S[x_1, \dots, x_n]$, where S is either $\mathbb{Z}$ or a field existing in `Maple`.)
- `Janet` [BCG⁺03] implements the involutive basis technique for computing JANET bases of linear systems of partial differential equations. (Differential algebras over differential fields: $K[\frac{\partial}{\partial x_1}, \dots, \frac{\partial}{\partial x_n}]$, where K is a differential field which exists in `Maple`.)
- `JanetOre` [Rob06, Rob07] generalizes `Involutive` from commutative polynomial rings to certain iterated skew polynomial rings. In particular, it computes Janet bases for left ideals in Ore algebras [CS98]. ($K[\partial; \sigma, \delta]$, where K is a polynomial ring over a field, ∂ a new indeterminate, σ is a certain automorphism of K and δ a σ -derivation of K , and iterated extensions of this kind.)
- `OreModules` [CQR07] is a `Maple` package for the study of structural properties of linear systems over ORE algebras, i.e. linear equations involving certain linear functional operators which can be considered as elements of an ORE algebra. By default, it uses the `Maple` package `Ore_algebra` [CS98] to compute GRÖBNER bases,

but these calls can also be switched to `JanetOre`. (ORE algebras [CS98] and the iterated skew polynomial rings from the previous point.)

`homalg` is also able to make use of various normal form algorithms for modules resp. special types of modules over various rings, which are used to provide a standard form for a presentation of these modules:

- `PIR` uses the `SMITH` normal form for (Maple-built-in) principal ideal rings.
- `Janet` optionally uses the `JACOBSON` normal form for univariate differential rings, i.e. rings of the form $K[\partial]$, where K is a differential field with ∂ a derivation of K .
- `Involutive` optionally uses the extension package `QuillenSuslin` written by ANNA FABIANSKA [Fab07, FQ07] implementing the `QUILLEN-SUSLIN` theorem to compute a free basis of a projective module over a polynomial ring (which is then free by the theorem). A similar extension package is planned for `OreModules`.
- `OreModules` optionally uses the extension package `Stafford` [QR] which computes a free basis for a stably free module of rank at least 2 over the Weyl algebras $k[x_1, \dots, x_n, \partial_1, \dots, \partial_n]$ and $k(x_1, \dots, x_n)[\partial_1, \dots, \partial_n]$, with k a field of characteristic 0.

APPENDIX B. THE Maple IMPLEMENTATION

B.1. Presentations. A presentation of a module in the current `Maple` implementation of `homalg` is a list¹⁹ containing as first entry the list of generators and as second entry the list of relations. The third entry is a string delimiter to optically indicate the end of the presentation. This string, unless changed by the user, defaults to "`Presentation`". The remaining entries provide extra information about the presented module, e.g. its `HILBERT` series in case the ring is the polynomial ring. This extra information can only be provided by the ring-specific package.

For $M = \text{coker}(\mathbf{M}) = R^{1 \times l_0} / R^{1 \times l_1} \mathbf{M}$ the list of the concrete generators are numbered by abstract generators being the l_0 standard basis row vectors of the underlying free module $R^{1 \times l_0}$. The list of relations simply contains the rows of the matrix $\mathbf{M}$. An illustration is given in Figure 1 of Example C.1.

B.2. The morphism part of functors. The name convention for functors used in the `Maple` implementation of `homalg` is as follows: If the procedure implementing the object part of a functor is called `F`, then the procedure implementing the morphism part is called `FMap`. It is defined using the procedure `FunctorMap` applied to the object part procedure `F`. The several pieces of code for the morphism part of the functors `Cokernel`, `Kernel`, `DefectOfHoms` and `Hom_R`, and the two bifunctors `TensorProduct` and `Hom`, reproduced on the web [BR07a], demonstrate how `FunctorMap` unifies the definition of the morphism part of *all* functors in `homalg`.

In future implementations of `homalg` the two procedures implementing the object and morphism part of a functor will be unified in one. The unified procedure will be able to

¹⁹In future implementations we will make use of object oriented data structures, which encapsulate all this information.

recognize if it has been applied to an object, to a morphism or even to complexes. This will be an easy task, once we strictly use structures throughout `homalg`.

B.3. Encapsulating functors. A functor is fully defined when both parts are defined, i.e. its object part and its morphism part. If the functor is a multi-functor, then several morphism parts have to be defined. `homalg` accesses all these parts of a functor via a so called encapsulation. It incorporates both parts and also takes care of the possible multi-functoriality. The implementation of the encapsulations of the functors `Hom_R`, `TensorProduct` and `Hom` can be viewed under [BR07a].

B.4. Composition of functors. As was mentioned in Section 5, composing two functors is an easy task since one simply has to compose their actions on objects and on morphisms. The procedure responsible for this is called `ComposeFunctors`. The implementation of the composition of the functors `HomHom_R` and `HomHom` can be viewed under [BR07a].

B.5. Applying functors to complexes. As mentioned in Section 7, functors should be applied to complexes of modules, rather than to single modules. Thereby `homalg` again makes use of the encapsulation of functors. In this implementation, there are two procedures depending on whether one is dealing with a covariant or a contravariant functor. They are called `FunctorOnSeqs` and `CofunctorOnSeqs`. The implementation of the functors `Hom` and `HomHom` on complexes can be viewed under [BR07a].

B.6. Derivation of functors. The left derivation procedure for covariant functors is called `LeftDerivedFunctor`. The faster derivation procedure for right exact functors, for example $- \otimes L$, referred to at the end of Subsection 7.1 is called `LeftDerived-RightExactFunctor`.

The right derivation procedure for contravariant functors is called `RightDerivedCofunctor`. The faster derivation procedure for left exact contravariant functors, for example $\text{Hom}(-, L)$, referred to at the end of Subsection 7.1 is called `RightDerivedLeftExact-Cofunctor`.

The implementation of the left derived functor `LHomHom` (of `HomHom` with respect to its first argument) and the right derived functor `Ext` (of `Hom` with respect to its first argument) can be viewed under [BR07a].

B.7. How FunctorMap works. Let `F` denote the object part procedure of a functor F . First `FunctorMap` asks `F` if the underlying functor is co- or contravariant. If `F` is `homalg`-basic it has to know the answer itself. If `F` is defined as a composition $F_1 \circ F_2$ then the question is passed to the procedure `ComposeFunctors`, which decides the answer by asking F_1 and F_2 (this is recursive). If `F` is defined as a derivation $L_q G$ or $R^q G$, using one of the derivation procedures, then `F` passes the question to the latter, which decides the answer by asking G (this is recursive). Any recursion ends when a `homalg`-basic functor is reached.

`FunctorMap` then asks `F` if it is defined using the procedure `ComposeFunctors`. If `F` is `homalg`-basic it ignores the question. If `F` is defined using one of the derivation procedures, the question is passed to the latter, which ignores it. If `F` is indeed defined as a composition $F_1 \circ F_2$, then `F` passes the question to `ComposeFunctors`, which returns the two functors F_1

and F_2 in both their parts. **FunctorMap** can now easily construct the morphism part of F by composing the morphism parts of F_1 and F_2 . In case F is not defined as a composition, **FunctorMap** asks it if it is defined by derivation. If F is **homalg**-basic it ignores the question. If F is indeed defined as a derivation $L_q G$ or $R^q G$, using one of the derivation procedures, then F passes the question to the latter, which returns the functor G in both its parts *and* a procedure based on **ResolutionOfSeq** to compute φ_q out of φ (cf. (Lift), p. 18). With these two ingredients **FunctorMap** is able to construct the morphism part of F as described in Subsection 7.2. If F is defined neither by composition nor by derivation, i.e. its is **homalg**-basic, then it is asked by **FunctorMap** to return²⁰ its hull functor Hull_F together with the natural embedding (cf. (Hull), p. 10). Again this suffices to construct the morphism part of F as described in Section 5.

APPENDIX C. EXAMPLES

For further examples we refer to [BR06a, BR06b] and the site of **homalg** [BR07c].

A nice application is the tiny **homalg**-based package **conley** that computes C -connection matrices of graded module octahedra/braids of Morse decompositions in dynamical system theory [BR].

For the sake of demonstration we wrote a tiny package called **alexander** [BR07b], which relies on **homalg** and computes simplicial homology and cohomology. Future implementations of **homalg** are planned to enable more serious applications to topology.

C.1. Example 1. In this example we compute a module of homomorphisms.

```
> restart;
```

```
> with(Involutive):  with(homalg):
```

Specify the **homalg**-table of the ring package **Involutive**:

```
> RPI:='Involutive/homalg';
```

$$RPI := Involutive/homalg$$

Use the ring package **Involutive** as the default ring package:

```
> 'homalg/default':=RPI;
```

$$homalg/default := Involutive/homalg$$

Define the ring $R = \mathbb{Q}[x, y, z]$:

```
> var:=[x,y,z];
```

$$var := [x, y, z]$$

```
> K:=Cokernel([[x,y,0],[x^2,y^2,0],[x^3,y^3,z^3]],var);
```

$$K := [[1, 0, 0] = [1, 0, 0], [0, 1, 0] = [0, 1, 0], [0, 0, 1] = [0, 0, 1],$$

$$[[x, y, 0], [0, x y - y^2, 0], [0, 0, z^3]], \text{ "Presentation"},$$

$$3 + 8 s + 14 s^2 + s^3 \left(\frac{14}{1-s} + \frac{6}{(1-s)^2} \right), [14, 6, 0]]$$

²⁰The technical details to realize this heavily depend on the implementation.

FIGURE 1. A module of homomorphisms between two modules over $R = \mathbb{Q}[x, y, z]$ with **Involutive**

$$\begin{array}{c}
 \begin{array}{l}
 \text{generators} \\
 \left| \begin{array}{l}
 \begin{array}{l}
 [[1, 0, 0] = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \end{bmatrix}, [0, 1, 0] = \begin{bmatrix} 0 & 0 & -y \\ 0 & 0 & x \end{bmatrix}, [0, 0, 1] = \begin{bmatrix} 0 & 0 & 0 \\ 0 & x-y & 0 \end{bmatrix}, \\
 [0, 0, y], [x^2 - xy, 0, -x], [0, z^3, 0], \\
 \text{"Presentation"}, \\
 3 + 8s + 14s^2 + s^3 \left(\frac{14}{(1-s)} + \frac{6}{(1-s)^2} \right), \\
 [14, 6, 0] \\
 \text{HILBERT series} \\
 \text{CARTAN characters}
 \end{array}
 \end{array}
 \end{array}
 \end{array}
 \end{array}$$

```
> L:=Cokernel([[x,y]],var);
```

$$\begin{aligned}
 L := & [[1, 0] = [1, 0], [0, 1] = [0, 1], [[x, y], \text{"Presentation"}, \\
 & 2 + s \left(\frac{2}{1-s} + \frac{2}{(1-s)^2} + \frac{1}{(1-s)^3} \right), [2, 2, 1]]
 \end{aligned}$$

Compute the module of homomorphisms $\text{Hom}_R(L, K)$ (see Figure 1):

```
> hom:=Hom(L,K,var);
```

$$\begin{aligned}
 \text{hom} := & [[[1, 0, 0] = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \end{bmatrix}, [0, 1, 0] = \begin{bmatrix} 0 & 0 & -y \\ 0 & 0 & x \end{bmatrix}, [0, 0, 1] = \begin{bmatrix} 0 & 0 & 0 \\ 0 & -y+x & 0 \end{bmatrix}], \\
 & [[0, 0, y], [x^2 - xy, 0, -x], [0, z^3, 0]], \text{"Presentation"}, \\
 & 3 + 8s + 14s^2 + s^3 \left(\frac{14}{1-s} + \frac{6}{(1-s)^2} \right), [14, 6, 0]]
 \end{aligned}$$

C.2. Example 2. Let $R := \mathbb{Q}[x, y, z]$. In this example we want to study two non-equivalent extensions $0 \rightarrow K \rightarrow M \rightarrow L \rightarrow 0$ and $0 \rightarrow K \rightarrow N \rightarrow L \rightarrow 0$ with K a torsion module and L a torsion free module. Our goal is to use the notion of functor to reveal that these extensions are not only non-equivalent but also non-isomorphic. For this we define two functors F_M and F_N and study their behavior when applied to complexes. Concretely, we apply F_M resp. F_N to $0 \rightarrow K \rightarrow M \rightarrow L \rightarrow 0$ which we refer to as

$$S : 0 \rightarrow K \xrightarrow{\alpha_1} M \xrightarrow{\alpha_2} L \rightarrow 0.$$

In the following we consider

$$F_Q = \text{Ext}(1, -, Q) = \text{Ext}^1(-, Q) = R^1 \text{Hom}_R(-, Q)$$

```
> restart;
```

```
> with(Involutive): with(homalg):
```

Use the ring package **Involutive** as the default ring package:

```
> RPI:='Involutive/homalg';
      RPI := Involutive/homalg
```

```
> 'homalg/default':=RPI;
      homalg/default := Involutive/homalg
```

We force the Maple ring package **Involutive** to use the external program JB, which is a C++ implementation of the involutive division algorithm:

```
> InvolutiveOptions("C++");
Define the ring  $R = \mathbb{Q}[x, y, z]$ :
```

```
> var:=[x,y,z];
      var := [x, y, z]
```

The two presentation matrices **M** and **N**:

```
> MM:=matrix([[x*z, z*y, z^2, 0, 0, y], [0, 0, 0, z^2*y-z^2, z^3, x*z],
> [0, 0, 0, z*y^2-z*y, z^2*y, x*y], [0, 0, 0, x*z*y-x*z, x*z^2, x^2],
> [-x*y, -y^2, -z*y, x^2*y-x^2-y+1, x^2*z-z, 0], [x^2*y-x^2, x*y^2-x*y,
> x*z*y-x*z, -y^3+2*y^2-y, -z*y^2+z*y, 0]]);
```

$$MM := \begin{bmatrix} xz & zy & z^2 & 0 & 0 & y \\ 0 & 0 & 0 & z^2y - z^2 & z^3 & xz \\ 0 & 0 & 0 & zy^2 - zy & z^2y & xy \\ 0 & 0 & 0 & xzy - xz & xz^2 & x^2 \\ -xy & -y^2 & -zy & x^2y - x^2 - y + 1 & x^2z - z & 0 \\ x^2y - x^2 & xy^2 - xy & xzy - xz & -y^3 + 2y^2 - y & -zy^2 + zy & 0 \end{bmatrix}$$

```
> NN:=matrix([[x*y, y^2, z*y, 0, 0, z], [0, 0, 0, z*y^2-z*y, z^2*y,
> x*z], [x^2*z, x*z*y, x*z^2, -z^2*y+z^2, -z^3, 0], [0, 0, 0,
> y^3-2*y^2+y, z*y^2-z*y, x*y-x], [0, 0, 0, x^2*y-x^2-y+1, x^2*z-z, y],
> [x^3, x^2*y, x^2*z, -x*z*y+x*z, -x*z^2, 0]]);
```

$$NN := \begin{bmatrix} xy & y^2 & zy & 0 & 0 & z \\ 0 & 0 & 0 & zy^2 - zy & z^2y & xz \\ x^2z & xzy & xz^2 & -z^2y + z^2 & -z^3 & 0 \\ 0 & 0 & 0 & y^3 - 2y^2 + y & zy^2 - zy & xy - x \\ 0 & 0 & 0 & x^2y - x^2 - y + 1 & x^2z - z & y \\ x^3 & x^2y & x^2z & -xzy + xz & -xz^2 & 0 \end{bmatrix}$$

The two modules $M := \text{coker} \left(R^{1 \times 6} \xrightarrow{M} R^{1 \times 6} \right)$ and $N := \text{coker} \left(R^{1 \times 6} \xrightarrow{N} R^{1 \times 6} \right)$:

```
> M:=Cokernel(MM,var);
```

$$\begin{aligned}
M := & [[[1, 0, 0, 0, 0, 0] = [1, 0, 0, 0, 0, 0], [0, 1, 0, 0, 0, 0] = [0, 1, 0, 0, 0, 0], \\
& [0, 0, 1, 0, 0, 0] = [0, 0, 1, 0, 0, 0], [0, 0, 0, 1, 0, 0] = [0, 0, 0, 1, 0, 0], \\

& [0, 0, 0, 0, 0, x^3y - x^3 - y^3 - xy + y^2 + x]], \text{ "Presentation",} \frac{3s}{1-s} + \frac{2}{(1-s)^2} + 2s^2 \\
& + \frac{3}{(1-s)^3} + \frac{2s^2}{(1-s)^2} + \frac{s^2}{1-s} + s^3 + \frac{1}{1-s} + \frac{s^3}{1-s} + \frac{s}{(1-s)^2}, [51, 17, 3]]
\end{aligned}$$

The torsion submodule $K := t(M)$ of M (and N):

> **K:=TorsionSubmodule(M,var);**

$$\begin{aligned}
K := & [[[1, 0, 0] = [0, 0, 0, 0, 0, 1], [0, 1, 0] = [0, 0, 0, y - 1, z, 0], [0, 0, 1] = [x, y, z, 0, 0, 0] \\
&], [[y, 0, z], [0, -zy, xz], [xz, z^2, 0], [0, -y^2 + y, xy - x], [xy, zy, 0], [0, x^2 - 1, -y], \\
& [x^2, xz, 0]], \text{ "Presentation", } s + \frac{1}{1-s} + \frac{s}{(1-s)^2} + \frac{2}{(1-s)^2} + \frac{s}{1-s}, [7, 3, 0]]
\end{aligned}$$

The embedding $0 \rightarrow K \xrightarrow{\alpha_1} M$:

> **alpha1:=TorsionSubmoduleEmb(M,var);**

$$\alpha 1 := \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & y-1 & z & 0 \\ x & y & z & 0 & 0 & 0 \end{bmatrix}$$

The torsion free factor $L := M/K = M/t(M)$ of M (and N):

> `L:=Cokernel(alpha1,M,var);`

$$\begin{aligned} L := & [[1, 0, 0, 0, 0] = [1, 0, 0, 0, 0, 0], [0, 1, 0, 0, 0] = [0, 1, 0, 0, 0, 0], \\ & [0, 0, 1, 0, 0] = [0, 0, 1, 0, 0, 0], [0, 0, 0, 1, 0] = [0, 0, 0, 1, 0, 0], \\ & [0, 0, 0, 0, 1] = [0, 0, 0, 0, 1, 0]], [[0, 0, 0, y-1, z], [x, y, z, 0, 0]], \text{ "Presentation",} \\ & \frac{2}{(1-s)^2} + \frac{3}{(1-s)^3}, [5, 5, 3]] \end{aligned}$$

The natural epimorphism $M \xrightarrow{\alpha 2} L \rightarrow 0$:

> `alpha2:=CokernelEpi(alpha1,M,var);`

$$\alpha 2 := \begin{bmatrix} 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix}$$

The short sequence $S : 0 \rightarrow K \xrightarrow{\alpha 1} M \xrightarrow{\alpha 2} L \rightarrow 0$ is exact:

> `IsShortExactSeq(K,alpha1,M,alpha2,L,var);`

true

The functor $\text{Ext}_R^1(-, N)$ applied to the short exact sequence S :

> `coseqN:=ExtOnSeqs(1,N,[alpha2,alpha1],[L,M,K],var):`

This says that the map $\text{Ext}_R^1(L, N) \xrightarrow{\text{Ext}_R^1(\alpha 2, N)} \text{Ext}_R^1(M, N)$ is not injective, i.e. that the connecting homomorphism $\text{Hom}_R(K, N) \xrightarrow{\delta^0} \text{Ext}_R^1(L, N)$ is non-trivial:

> `IsShortExactSeq(op(MakeCoseq(coseqN)),var,"VERBOSE");`

"homs" = *true*, "cmps" = *true*, "defs" =

$$[[[1 = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix}], [z, y, x], \text{ "Presentation", } 1, [0, 0, 0]], \text{ true, true}]$$

The functor $\text{Ext}_R^1(-, M)$ applied to the short exact sequence S :

> `coseqM:=ExtOnSeqs(1,M,[alpha2,alpha1],[L,M,K],var):`

Whereas the resulting sequence $\text{Ext}_R^1(S, M)$ is again exact. In particular, the connecting homomorphism $\text{Hom}_R(K, M) \xrightarrow{\delta^0} \text{Ext}_R^1(L, M)$ is trivial, i.e. the zero map:

> `IsShortExactSeq(op(MakeCoseq(coseqM)),var,"VERBOSE");`

true

C.3. Example 3. This example demonstrates by a computation over a noncommutative ORE domain how one can use `homalg` to solve a linear system of differential-difference equations:

```
> restart;
```

```
> with(JanetOre): with(homalg):
```

Specify the `homalg`-table of the ring package `JanetOre`:

```
> RP0:='JanetOre/homalg';
```

$$RPO := JanetOre/homalg$$

Use the ring package `JanetOre` as the default ring package:

```
> 'homalg/default':=RP0;
```

$$homalg/default := JanetOre/homalg$$

Ask `homalg` to check if a stably free module with a *finite free* resolution²¹ is free, cf. [QR, Remark 51]:

```
> homalg_options("check_rank_1"=true);
```

“JanetOre/homalg”, “check_if_stably_free_rank_1_FFR_is_free” = *true*

Define the ORE domain $R = \mathbb{Q}[t][D, t \mapsto t, \frac{d}{dt}][\delta, t \mapsto t + 1, 0]$:

```
> Ore:=[[t,D,delta],[],[weyl(D,t),shift(delta,t)]];
Ore := [[t, D, delta], [], [weyl(D, t), shift(delta, t)]]
```

Find the general solution to the following linear system of differential-difference equations:

$$\begin{aligned} u(t) + u(t+2) + D(v)(t+1) - v(t+2) + w(t+1) &= 0, \\ tD(u)(t+1) + u(t+3) - 2tu(t+1) + 2D(u)(t+1) - 2u(t+1) \\ &\quad - v(t+3) + 2v(t+2) + w(t+2) = 0. \end{aligned}$$

This system can be written as the following matrix operators A applied to the section $\begin{pmatrix} u(t) & v(t) & w(t) \end{pmatrix}^{\text{tr}}$. (Caution: A monomial in t , D and δ must be read as a monomial with powers of t on the left of a monomial in the commuting D and δ : read in the following both tD , Dt as tD , and both $t\delta$, δt as $t\delta$):

```
> A := matrix([[1+delta^2, delta*D-delta^2, delta],
> [t*delta*D+delta^3-2*t*delta+2*delta*D-2*delta, -delta^3+2*delta^2,
> delta^2]]);
```

$$A := \begin{bmatrix} 1 + \delta^2 & \delta D - \delta^2 & \delta \\ t\delta D + \delta^3 - 2t\delta + 2\delta D - 2\delta & -\delta^3 + 2\delta^2 & \delta^2 \end{bmatrix}$$

Studying the system is equivalent to studying the cokernel M of $A \in R^{m \times n}$ viewed as a morphism $R^{1 \times m} \xrightarrow{A} R^{1 \times n}$. This is based on the following observation: Let $\mathcal{F}$ be a function space, where one wants to search for solutions of the system, then $\text{Hom}_R(\text{coker}(A), \mathcal{F}) \cong \text{Sol}_{\mathcal{F}}(A) := \{\eta \in \mathcal{F}^{n \times 1} \mid A\eta = 0\}$, where n is the number of columns of A .

²¹Without a finite free resolution `homalg` cannot check stably freeness, cf. [QR, Remark 28].

> `M:=Cokernel(A,Ore);`

$$M := [[[1, 0, 0] = [1, 0, 0], [0, 1, 0] = [0, 1, 0], [0, 0, 1] = [0, 0, 1]], \\ [[1 + \delta^2, \delta D - \delta^2, \delta], [t\delta D + \delta^3 - 2t\delta + 2\delta D - 2\delta, -\delta^3 + 2\delta^2, \delta^2]], \\ \text{"Presentation"}, 3 + 9s + 17s^2 + s^3(\frac{17}{1-s} + \frac{8}{(1-s)^2} + \frac{1}{(1-s)^3}), [17, 8, 1]]$$

The torsion free factor F of M turns out to be free of rank 1 (the above mentioned option "`check_rank_1`" was used):

> `F:=TorsionFreeFactor(M,Ore);`

$$F := [[1 = [-\delta, \delta - D, -1]], [0], \text{"Presentation"}, \frac{1}{(1-s)^3}, [0, 0, 1]]$$

The natural epimorphsim $M \xrightarrow{\nu} F$:

> `nu:=TorsionFreeFactorEpi(M,Ore);`

$$\nu := \begin{bmatrix} \delta \\ t \\ -2 + \delta + t\delta - tD - \delta^2 \end{bmatrix}$$

Since F is free one can use `Leftinverse` to compute a split $M \xrightarrow{\chi} F$ (cf. 3.1.3,(1)):

> `chi:=Leftinverse(M,nu,F,Ore);`

$$\chi := \begin{bmatrix} -\delta & \delta - D & -1 \end{bmatrix}$$

Now compute the torsion submodule T of M :

> `T:=TorsionSubmodule(M,Ore);`

$$T := [[[1, 0] = [t + 1, -\delta, 0], [0, 1] = [-2\delta, -t\delta + tD + \delta^2 + 1, t]], \\ [[1 + \delta^2, \delta], [-2 + D, -2\delta + \delta D], [-2\delta + \delta D, 0]], \text{"Presentation"}, \\ 2 + 6s + s^2(\frac{6}{1-s} + \frac{3}{(1-s)^2}), [6, 3, 0]]$$

And the natural embedding $T \xrightarrow{\iota} M$:

> `iota:=TorsionSubmoduleEmb(M,Ore);`

$$\iota := \begin{bmatrix} t + 1 & -\delta & 0 \\ -2\delta & -t\delta + tD + \delta^2 + 1 & t \end{bmatrix}$$

After a few tests we found an element $\mu \in T$

> `mu:=[[delta,1]];`

$$\mu := [[\delta, 1]]$$

which turned out to be a cyclic generator of T (below one identifies μ with the morphism $R^{1 \times 1} \rightarrow T : 1 \mapsto \mu$):

> `IsSurjective(mu,T,Ore);`

true

H is nothing but T rewritten on this cyclic generator. It further turns out that the cyclic generator μ of the torsion submodule T satisfies a single simple relation $\delta^2(D - 2)\mu = 0$:

> $H := \text{Image}(\mu, T, \text{Ore});$

$$H := [[1 = [t\delta, tD - t\delta + 1, t]], [-2\delta^2 + \delta^2 D], \text{ "Presentation" }, \\ 1 + 3s + 6s^2 + s^3(\frac{6}{1-s} + \frac{3}{(1-s)^2}), [6, 3, 0]]$$

ε is nothing but ι rewritten on the cyclic generator μ :

> $\text{epsilon} := \text{ComposeMaps}(\mu, \iota, M, \text{Ore});$

$$\varepsilon := \begin{bmatrix} t\delta & tD - t\delta + 1 & t \end{bmatrix}$$

> $\text{IsHom}(H, \text{epsilon}, M, \text{Ore});$

true

> $\text{IsInjective}(H, \text{epsilon}, M, \text{Ore});$

true

Now construct the isomorphism α from the direct sum $S := F \oplus H$ onto M :

> $\alpha := \text{RPO}[\text{matrix}](\text{RPO}[\text{UnionOfRows}](\chi, \text{epsilon}));$

$$\alpha := \begin{bmatrix} -\delta & \delta - D & -1 \\ t\delta & tD - t\delta + 1 & t \end{bmatrix}$$

> $S := \text{DirectSum}(F, H, \text{Ore});$

$$S := [[[1, 0] = [1, 0], [0, 1] = [0, 1]], [[0, -2\delta^2 + \delta^2 D], \text{ "Presentation" }, \\ 2 + 6s + 12s^2 + s^3(\frac{12}{1-s} + \frac{6}{(1-s)^2} + \frac{1}{(1-s)^3}), [12, 6, 1]]$$

> $\text{IsHom}(S, \alpha, M, \text{Ore});$

true

> $\text{IsBijective}(S, \alpha, M, \text{Ore});$

true

N is now nothing but M rewritten on the images of the two generators of S . So M (or N) is a module generated by two generators, one free and one subject to a single simple relation:

> $N := \text{Image}(\alpha, M, \text{Ore});$

$$N := [[[1, 0] = [-\delta, \delta - D, -1], [0, 1] = [t\delta, tD - t\delta + 1, t]], [[0, -2\delta^2 + \delta^2 D], \\ \text{ "Presentation" }, 2 + 6s + 12s^2 + s^3(\frac{12}{1-s} + \frac{6}{(1-s)^2} + \frac{1}{(1-s)^3}), [12, 6, 1]]$$

Using sections, the above presentation reads: The original system on the three unknown functions $u(t)$, $v(t)$ and $w(t)$ is equivalent to a system on two unknown functions $f(t)$ and $g(t)$, where only $g(t)$ satisfies the single simple equation $D(g)(t+1) - g(t+1) = 0$. It is also given how to express f and g in terms of u , v and w .

> `PresentationOnSections(N,Ore[1],Ore[3],[u,v,w],[f,g]);`

$[[f(t) = -u(t+1) + v(t+1) - D(v)(t) - w(t),$
 $g(t) = t u(t+1) + t D(v)(t) - t v(t+1) + v(t) + t w(t)], [-2g(t+2) + D(g)(t+2)],$
 "Presentation", $2 + 6s + 12s^2 + s^3(\frac{12}{1-s} + \frac{6}{(1-s)^2} + \frac{1}{(1-s)^3})$, $[12, 6, 1]]$

$f(t)$ is therefore a free function and $g(t) = C \exp(t)$, where C is an arbitrary constant:

> `sol:=[f=unapply(f(t),t),g=unapply(C*exp(2*t),t)];`

$sol := [f = (t \rightarrow f(t)), g = (t \rightarrow C e^{(2t)})]$

In order to solve the original system one needs to express u , v and w in terms of f and g . To this end use `Leftinverse` to compute $\eta := \alpha^{-1}$ (cf. 3.1.3,(2)):

> `eta:=Leftinverse(S,alpha,M,Ore);`

$$\eta := \begin{bmatrix} \delta & 0 \\ t & 1 \\ -2 + \delta + t\delta - tD - \delta^2 & \delta - D \end{bmatrix}$$

Again, L is nothing but $S (\cong M)$ rewritten on the images (under η) of the three original generators of M :

> `L:=Image(eta,S,Ore,"USE_IMAGE_OF_GENERATORS");`

$L := [[[1, 0, 0] = [\delta, 0], [0, 1, 0] = [t, 1], [0, 0, 1] = [-2 + \delta + t\delta - tD - \delta^2, \delta - D]],$
 $[[1 + \delta^2, \delta D - \delta^2, \delta], [t\delta D + \delta^3 - 2t\delta + 2\delta D - 2\delta, -\delta^3 + 2\delta^2, \delta^2]],$
 "Presentation", $3 + 9s + 17s^2 + s^3(\frac{17}{1-s} + \frac{8}{(1-s)^2} + \frac{1}{(1-s)^3})$, $[17, 8, 1]]$

And again, using the `JanetOre` procedure `PresentationOnSections`, the above presentation is rewritten:

> `P:=PresentationOnSections(L,Ore[1],Ore[3],[f,g],[u,v,w]);`

$P := [[u(t) = f(t+1), v(t) = t f(t) + g(t),$
 $w(t) = -2f(t) + f(t+1) + t f(t+1) - t D(f)(t) - f(t+2) + g(t+1) - D(g)(t)], [$
 $u(t) + u(t+2) + D(v)(t+1) - v(t+2) + w(t+1), t D(u)(t+1) + u(t+3)$
 $- 2t u(t+1) + 2 D(u)(t+1) - 2u(t+1) - v(t+3) + 2v(t+2) + w(t+2)],$
 "Presentation", $3 + 9s + 17s^2 + s^3(\frac{17}{1-s} + \frac{8}{(1-s)^2} + \frac{1}{(1-s)^3})$, $[17, 8, 1]]$

The most general $C^\infty(\mathbb{R})$ -solution is given by:

> `Sol:=eval(RPO[matrix](GeneratorsOfPresentation(P)),sol);`

$$Sol := \begin{bmatrix} f(t+1) \\ t f(t) + C e^{(2t)} \\ -2f(t) + f(t+1) + t f(t+1) - t D(f)(t) - f(t+2) + C e^{(2t+2)} - 2C e^{(2t)} \end{bmatrix}$$

Besides, one has the following uniqueness property: If $\tilde{f}$ and $\tilde{C}$ lead to the same solution then $\tilde{f} = f$ and $\tilde{C} = C$.

Test the general solution with the JanetOre procedure `JApplyMatrix`:

```
> JApplyMatrix(A,Sol,Ore[1],Ore[3]);
```

$$\begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
